Preface

The ongoing success of the earlier versions of this book motivated us to prepare a new edition. While modern techniques of nuclear magnetic resonance spectroscopy and mass spectrometry have changed the ways of data acquisition and greatly extended the capabilities of these methods, the basic parameters, such as chemical shifts, coupling constants, and fragmentation pathways remain the same. However, since the amount and quality of available data has considerably increased over the years, we decided to prepare a significantly revised manuscript. It follows the same basic concepts, i.e., it provides a representative, albeit limited set of reference data for the interpretation of ^{13}C NMR, ^1H NMR, IR, mass, and UV/Vis spectra. We also added a new chapter with reference data for ^{19}F and ^{31}P NMR spectroscopy and, in the chapter on infrared spectroscopy, we newly refer to important Raman bands.

Since operating systems of computers become outdated much faster than printed media, we decided against providing a compact disk with this new edition. The limited versions of the NMR spectra estimation programs can be downloaded from the home page of the developing company (www.upstream.ch/support/book_downloads.html).

We thank numerous colleagues who helped us in many different ways to complete the manuscript. We are particularly indebted to Dr. Dorothée Wegmann for her expertise with which she eliminated many errors and inconsistencies of the earlier versions. Special thanks are due to Prof. Wolfgang Robien for providing us with reference data from his outstanding ^{13}C NMR database, CSEARCH. Another high-quality source of information was the Spectral Database System of the National Institute of Advanced Industrial Science and Technology (<http://riodb01.ibase.aist.go.jp/sdbs/>), Tsukuba, Ibaraki (Japan).

In spite of great efforts and many checks to eliminate errors, it is likely that some mistakes or inconsistencies remain. We would like to encourage our readers to contact us with comments and suggestions under one of the following addresses: Prof. Ernö Pretsch, Institute of Biogeochemistry and Pollutant Dynamics, ETH Zürich, CH-8092 Zürich, Switzerland, e-mail: pretzsche@ethz.ch, Prof. Philippe Bühlmann, Department of Chemistry, University of Minnesota, 207 Pleasant St. SE, Minneapolis, MN 55455, USA, e-mail: buhlmann@umn.edu, or Dr. Martin Badertscher, Laboratory of Organic Chemistry, ETH Zürich, CH-8093 Zürich, Switzerland, e-mail: badertscher@org.chem.ethz.ch.

1 Introduction

1.1 Scope and Organization

The present data collection is intended to serve as an aid in the interpretation of molecular spectra for the elucidation and confirmation of the structure of organic compounds. It consists of reference data, spectra, and empirical correlations from ^1H , ^{13}C , ^{19}F , and ^{31}P nuclear magnetic resonance (NMR), infrared (IR), mass, and ultraviolet–visible (UV/Vis) spectroscopy. It is to be viewed as a supplement to textbooks and specific reference works dealing with these spectroscopic techniques. The use of this book to interpret spectra only requires the knowledge of basic principles of the techniques, but its content is structured in a way that it will serve as a reference book also to specialists.

Chapters 2 and 3 contain Summary Tables and Combined Tables of the most relevant spectral characteristics of structural elements. While Chapter 2 is organized according to the different spectroscopic methods, Chapter 3 for each class of structural elements supplies spectroscopic information obtained with various techniques. These two chapters should assist users less familiar with spectra interpretation to identify the classes of structural elements present in samples of their interest. The four chapters with data from ^{13}C NMR, ^1H NMR, IR spectroscopy, and mass spectrometry are ordered in the same manner by compound types. These cover the various carbon skeletons (alkyl, alkenyl, alkynyl, alicyclic, aromatic, and heteroaromatic), the most important substituents (halogen, single-bonded oxygen, nitrogen, sulfur, and carbonyl), and some specific compound classes (miscellaneous compounds and natural products). Finally, a spectra collection of common solvents, auxiliary compounds (such as matrix materials and references), and commonly found impurities is provided with each method. Not only the strictly analogous order of the data but also the optical marks on the edge of the pages help fast cross-referencing between the various spectroscopic techniques. Because their data sets are less comprehensive, the chapters on ^{19}F and ^{31}P NMR and UV/Vis are organized somewhat differently. Although currently UV/Vis spectroscopy is only marginally relevant to structure elucidation, its importance might increase by the advent of high-throughput analyses. Also, the reference data presented in the UV/Vis chapter are useful in connection with optical sensors and the widely applied UV/Vis detectors in chromatography and electrophoresis.

Since a great part of the tabulated data either comes from our own measurements or is based on a large body of literature data, comprehensive references to published sources are not included. Whenever possible, the data refer to conventional modes and conditions of measurement. For example, unless the solvent is indicated, the NMR chemical shifts were normally determined with deuteriochloroform. Likewise, the IR spectra were measured using solvents of low polarity, such as chloroform or

carbon disulfide. Mass spectral data were recorded with electron impact ionization at 70 eV.

While retaining the basic structure of the previous editions, numerous reference entries have been updated and new entries have been added. Altogether, about 20% of the data is new. The chapter on ^{19}F and ^{31}P NMR is entirely new, and the section on IR spectroscopy now includes references to important Raman bands.

1.2 Abbreviations and Symbols

al	aliphatic
alk	alkyl
alken	alkenyl
ar	aromatic
as	asymmetric
ax	axial
comb	combination vibration
d	doublet
δ	IR: deformation vibration NMR: chemical shift
DFTMP	1,1-difluoro-1-(trimethylsilyl)methylphosphonic acid
DMSO	dimethyl sulfoxide
eq	equatorial
ϵ	molar absorptivity
frag	fragment
γ	skeletal vibration
gem	geminal
hal	halogen
ip	in plane vibration
J	coupling constant
liq	liquid
$M^{+}\cdot$	molecular radical ion
m/z	mass to charge ratio
$\tilde{\nu}$	wavenumber
oop	out of plane vibration
sh	shoulder
st	stretching vibration
sy	symmetric
TFA	trifluoroacetic acid
THF	tetrahydrofuran
TMS	tetramethylsilane
vic	vicinal

2 Summary Tables

2.1 General Tables

2.1.1 Calculation of the Number of Double Bond Equivalents from the Molecular Formula

General Equation

$$\text{double bond equivalents} = 1 + \frac{1}{2} \sum_i n_i (v_i - 2)$$

n_i : number of atoms of element i in molecular formula

v_i : formal valence of element i

Short Cut

For compounds containing only C, H, O, N, S, and halogens, the following steps permit a quick and simple calculation of the number of double bond equivalents:

1. O and divalent S are deleted from the molecular formula
2. Halogens are replaced by hydrogen
3. Trivalent N is replaced by CH
4. The resulting hydrocarbon, C_nH_x , is compared with the saturated hydrocarbon, C_nH_{2n+2} . Each double bond equivalent reduces the number of hydrogen atoms by 2:

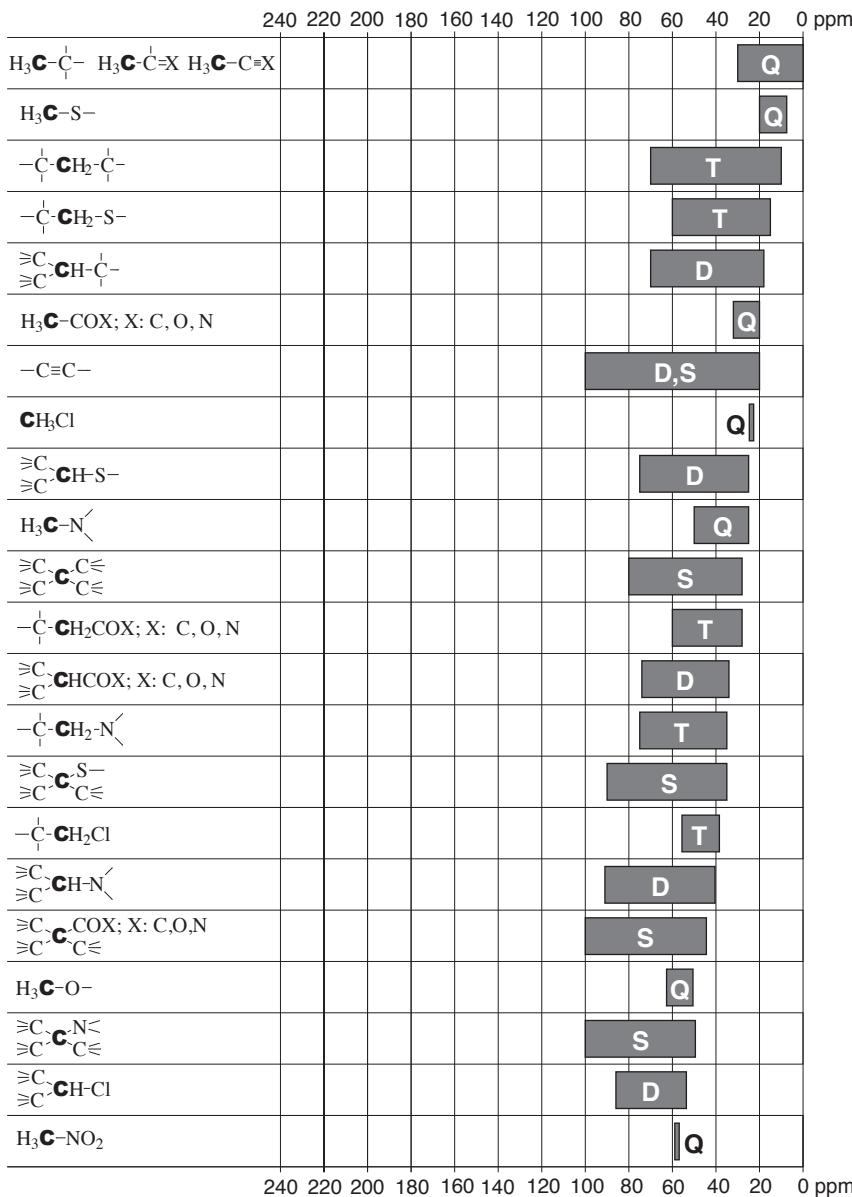

$$\text{double bond equivalents} = \frac{1}{2} (2n + 2 - x)$$

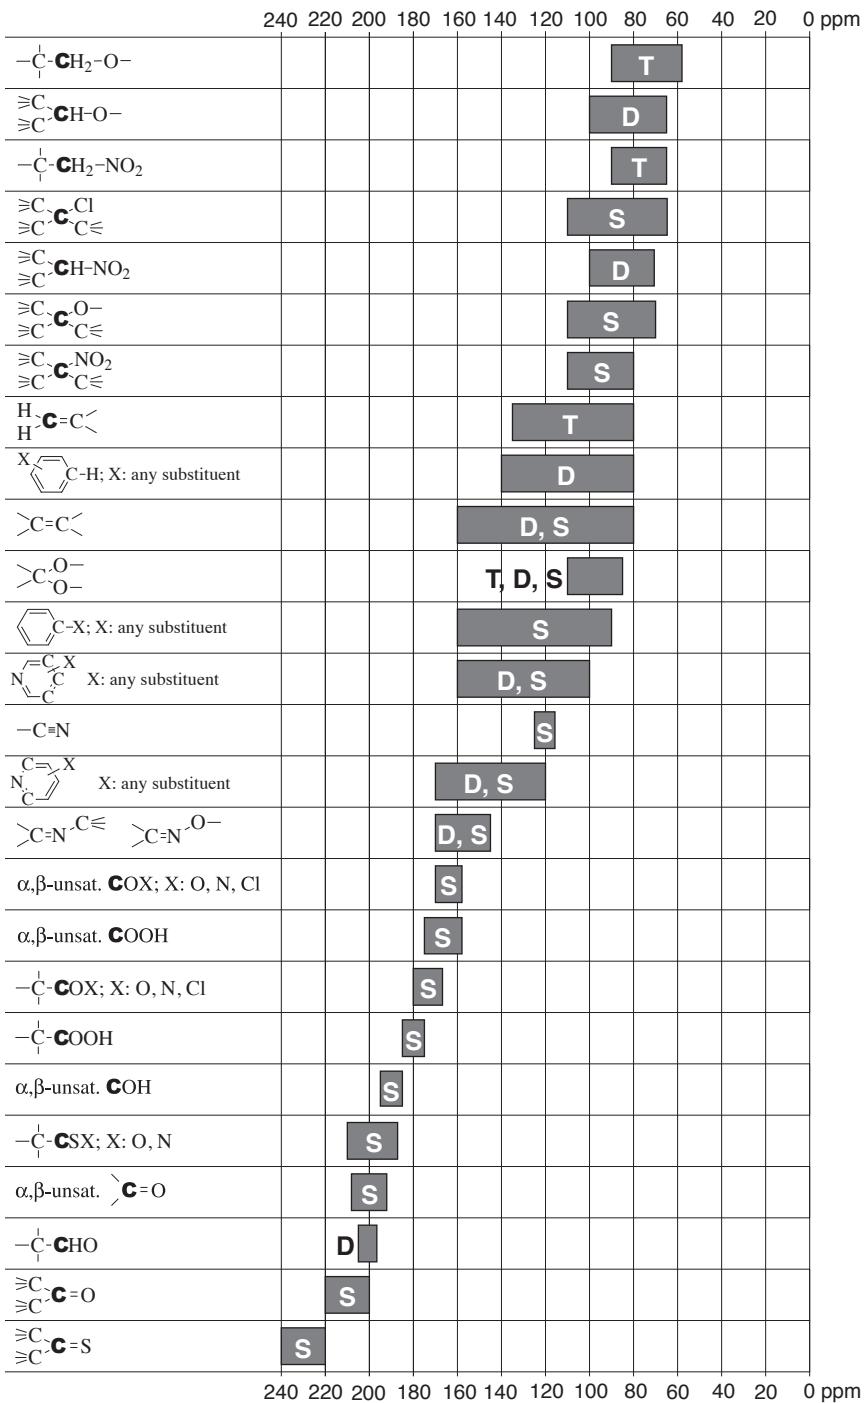

2.1.2 Properties of Selected Nuclei

Isotope	Natural abundance [%]	Spin quantum number, I	Frequency [MHz] at 2.35 Tesla	Relative sensitivity of nucleus	Relative sensitivity at natural abundance	Electric quadrupole moment [$e \times 10^{-24} \text{ cm}^2$]
¹ H	99.985	1/2	100.0	1	1	
² H	0.015	1	15.4	9.6×10^{-3}	1.5×10^{-6}	2.8×10^{-3}
³ H	0.000	1/2	106.7	1.2	0

^a Natural variations in the isotopic composition of terrestrial materials do not allow to give a more precise value.

^b The mole ratio of ²H in hydrogen from gas cylinders was reported to be as low as 0.000032.

^c Commercially available materials may have substantially different isotopic compositions if they were subjected to undisclosed or inadvertent isotopic fractionation.

^d Materials depleted in ⁶Li are commercial sources of laboratory shelf reagents and are known to have ⁶Li abundances in the range of 2.0007–7.672 atom percent, with natural materials at the higher end of this range. Average atomic masses vary between 6.939 and 6.996; if a more accurate value is required, it must be determined for the specific material.

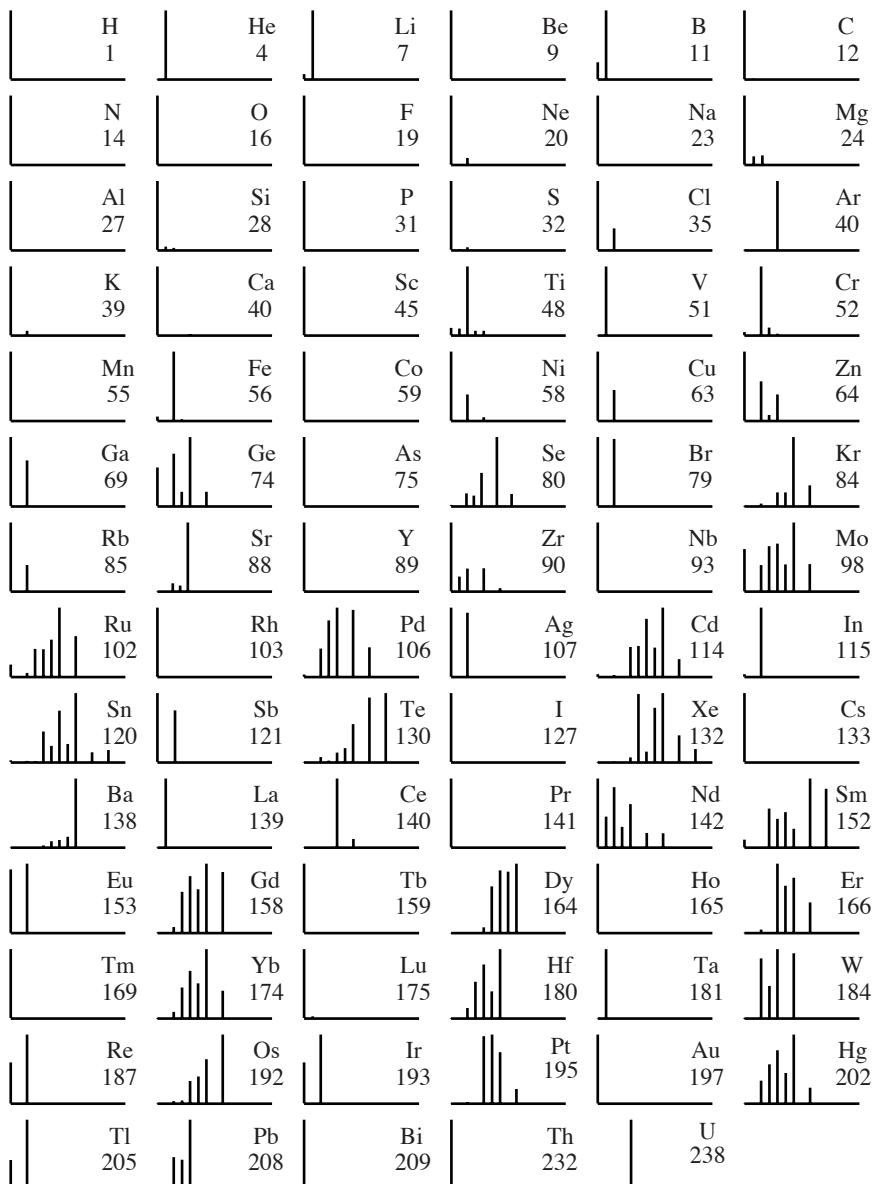

^e Materials depleted in ²³⁵U are commercial sources of laboratory shelf reagents.

2.5.2 Ranges of Natural Isotope Abundances of Selected Elements [3]

Element	Range	Element	Range	Element	Range
Isotope	[atom %]	Isotope	[atom %]	Isotope	[atom %]

2.5.3 Isotope Patterns of Naturally Occurring Elements

The mass of the most abundant isotope is given under the symbol of the element. The lightest isotope is shown at the left end of the x axis.

2.5.4 Calculation of Isotope Distributions

The characteristic abundance patterns resulting from the combination of more than one polyisotopic element can be calculated from the relative abundances of the different isotopes. The following polynomial expression gives the isotope distribution of a polyisotopic molecule:

$$\{p_{i1} A^0 + p_{i2} A^{(m_{i2} - m_{i1})} + p_{i3} A^{(m_{i3} - m_{i1})} + \dots\}^{n_i} \times \\ \{p_{j1} A^0 + p_{j2} A^{(m_{j2} - m_{j1})} + p_{j3} A^{(m_{j3} - m_{j1})} + \dots\}^{n_j} \times \dots$$

where p_{ix} is the relative abundance of the x th isotope of element i , m_{ix} is the mass of the x th isotope of the element i , and the exponent n_i stands for the number of atoms of the element i in the molecule. The expansion of this polynomial expression after inserting the p_{ix} and m_{ix} values for all the isotopes 1, 2, 3, ... of the elements i, j, \dots of a given molecule yields an expression that represents the isotope distribution:

$$w_0 A^0 + w_r A^r + w_s A^s + w_t A^t + \dots$$

where the values of $w_0, w_r, w_s, w_t, \dots$ are the relative abundances of M^+ , $[M+r]^{++}$, $[M+s]^{++}$, $[M+t]^{++}, \dots$, respectively. The use of $A^{(m_{ix} - m_{i1})}$ allows to determine the values of r, s, t, \dots simply by expanding the general polynomial. A numerical value for A , which has no intrinsic meaning, is never needed.

For example, for CBr_2Cl_2 , the above equation gives rise to the following expression:

$$\{p_{12C} A^0 + p_{13C} A^{(m_{13C} - m_{12C})}\} \times \\ \{p_{79Br} A^0 + p_{81Br} A^{(m_{81Br} - m_{79Br})}\}^2 \times \\ \{p_{35Cl} A^0 + p_{37Cl} A^{(m_{37Cl} - m_{35Cl})}\}^2$$

For sufficient resolution, $(m_{ix} - m_{i1})$ and $(m_{jx} - m_{j1})$ differ from one another. This results in very complex isotope patterns even for very small molecules. Thus, owing to the occurrence of ^{12}C , ^{13}C , ^{79}Br , ^{81}Br , ^{35}Cl , and ^{37}Cl , there are 18 signals for CBr_2Cl_2 . However, the limited resolution of many real life experiments can make many pairs of $(m_{ix} - m_{i1})$ and $(m_{jx} - m_{j1})$ indistinguishable within experimental error, thereby reducing the number of separate peaks. For example, at unit resolution, one obtains $(m_{13C} - m_{12C}) = 1$ and $(m_{81Br} - m_{79Br}) = (m_{37Cl} - m_{35Cl}) = 2$. Consequently, the expression for CBr_2Cl_2 becomes:

$$\begin{aligned}
& \{ p_{12C} A^0 + p_{13C} A^1 \} \times \{ p_{79Br} A^0 + p_{81Br} A^2 \}^2 \times \{ p_{35Cl} A^0 + p_{37Cl} A^2 \}^2 = \\
& \{ p_{12C} p_{79Br}^2 p_{35Cl}^2 \} A^0 + \\
& \{ p_{13C} p_{79Br}^2 p_{35Cl}^2 \} A^1 + \\
& \{ p_{12C} p_{79Br} p_{81Br} p_{35Cl}^2 + p_{12C} p_{79Br}^2 p_{35Cl} p_{37Cl} \} A^2 + \\
& \{ p_{13C} p_{79Br} p_{81Br} p_{35Cl}^2 + p_{13C} p_{79Br}^2 p_{35Cl} p_{37Cl} \} A^3 + \\
& \{ p_{12C} p_{81Br} p_{35Cl}^2 + 4 p_{12C} p_{79Br} p_{81Br} p_{35Cl} p_{37Cl} + p_{12C} p_{79Br}^2 p_{37Cl}^2 \} A^4 + \\
& \{ p_{13C} p_{81Br} p_{35Cl}^2 + 4 p_{13C} p_{79Br} p_{81Br} p_{35Cl} p_{37Cl} + p_{13C} p_{79Br}^2 p_{37Cl}^2 \} A^5 + \\
& \{ p_{12C} p_{79Br} p_{81Br} p_{37Cl}^2 + p_{12C} p_{81Br}^2 p_{35Cl} p_{37Cl} \} A^6 + \\
& \{ p_{13C} p_{79Br} p_{81Br} p_{37Cl}^2 + p_{13C} p_{81Br}^2 p_{35Cl} p_{37Cl} \} A^7 + \\
& \{ p_{12C} p_{81Br} p_{37Cl}^2 \} A^8 + \\
& \{ p_{13C} p_{81Br} p_{37Cl}^2 \} A^9
\end{aligned}$$

This shows that at unit resolution, CBr_2Cl_2 gives rise to only 10 peaks (M^+ , $[M+1]^+$, $[M+2]^+$, ... $[M+9]^+$) rather than 18 peaks, as they would be expected for very high resolution. Moreover, the contribution of isotopes of low abundance can often be neglected without sacrificing much precision. For example, the effect of ${}^2\text{H}$ on isotope patterns is usually insignificant. Also, ${}^{13}\text{C}$ is often negligible when focussing on peaks of the series $[M+2n]^+$, which then results in patterns that are characteristic for halogens, sulfur, and silicon. In large molecules, however, isotopes of low abundance cannot be neglected. For example, in the case of buckminster fullerene (C_{60}), not only M^+ (relative intensity, 100%) and $[M+1]^+$ (64.80%), but also $[M+2]^+$ (20.65%), $[M+3]^+$ (4.31%), and even $[M+4]^+$ (0.66%) are quite significant ions.

With the above algorithm, typical isotope patterns can be readily calculated manually by applying the general equation and neglecting isotopes of low abundance. The outlined procedure can also be easily implemented and evaluated with generic computer software that allows simple calculations. Dedicated and user-friendly programs that already contain the necessary isotope abundances and masses are available. Incidentally, because the use of the above equation for systems with 1000 or more polyisotopic atoms results in excessive calculation times, more efficient but somewhat more complicated algorithms have been developed for implementation in dedicated programs [4]. Typical isotope patterns are given on the following pages.

2.5.5 Isotopic Abundances of Various Combinations of Chlorine, Bromine, Sulfur, and Silicon

Ele- ments	Mass	Relative abun- dance	Ele- ments	Mass	Relative abun- dance	Ele- ments	Mass	Relative abun- dance

2.5.6 Isotope Patterns of Combinations of Cl and Br

The signals are separated by 2 mass units. The mass for the most abundant signal is shown under the symbol of the element. The combination of the lightest isotopes is given on the left side of the x axis. See Chapter 2.5.5 for exact abundances of many of these combinations.

2.5.7 Indicators of the Presence of Heteroatoms

In low-resolution mass spectra, one often observes characteristic isotope patterns, specific masses of fragment ions, and characteristic mass differences (Δm) between the molecular ion (M^{+*}) and fragment ions (frag^+) or between fragment ions. High resolution mass spectra can be used to confirm the elemental composition provided that the resolution is sufficient to discriminate alternative compositions. Moreover, tandem mass spectrometry (also called MS/MS) may be used to identify characteristic losses of heteroatoms from parent or fragment ions:

- Indication of O: Δm 17 from M^{+*} , in N-free compounds
 Δm 18 from M^{+*}
 Δm 18 from frag^+ , particularly in aliphatic compounds
 Δm 28, 29 from M^{+*} for aromatic compounds
 Δm 28 from frag^+ for aromatic compounds
m/z 15, relatively abundant
m/z 19
m/z 31, 45, 59, 73, ... + $(14)_n$
m/z 32, 46, 60, 74, ... + $(14)_n$
m/z 33, 47, 61, 75, ... + $(14)_n$ for $2 \times O$, in absence of S
m/z 69 for aromatic compounds meta-disubstituted by O
- Indication of N: M^{+*} odd-numbered (indicates odd number of N in M^{+*})
Large number of even-numbered fragment ions
 Δm 17 from M^{+*} or frag^+ , in O-free compounds
 Δm 27 from M^{+*} or frag^+ , for aromatic compounds or nitriles
 Δm 30, 46 for nitro compounds
m/z 30, 44, 58, 72, ... + $(14)_n$ for aliphatic compounds
- Indication of S: Isotope peak $[M+2]^{+*} \geq 5\%$ of M^{+*}
 Δm 33, 34, 47, 48, 64, 65 from M^{+*}
 Δm 34, 48, 64 from frag^+
m/z 33, 34, 35
m/z 45 in O-free compounds
m/z 47, 61, 75, 89, ... + $(14)_n$ unless compound with $2 \times O$
m/z 48, 64 for S-oxides
- Indication of F: Δm 19, 20, 50 from M^{+*}
 Δm 20 from frag^+
m/z 20
m/z 57 without m/z 55 in aromatics

Indication of Cl: Isotope peak $[M+2]^{+} \geq 33\%$ of M^{+}

Δm 35, 36 from M^{+}

Δm 36 from $frag^{+}$

m/z 35/37, 36/38, 49/51

Indication of Br: Isotope peak $[M+2]^{+} \geq 98\%$ of M^{+}

Δm 79, 80 from M^{+}

Δm 80 from $frag^{+}$

m/z 79/81, 80/82

Indication of I: Isotope peak $[M+1]^{+}$ of very low abundance at relatively high mass

Δm 127 from M^{+}

Δm 127, 128 from $frag^{+}$

m/z 127, 128, 254

Indication of P: m/z 47 in compounds without S or $2 \times O$

m/z 99 without isotope peak at m/z 100 in alkyl phosphates

2.5.8 Rules for Determining the Relative Molecular Weight (M_r)

The molecular ion (M^{+*}) is defined as the ion that comprises the most abundant isotopes of the elements in the molecule. Interestingly, the lightest isotopes of most elements frequently occurring in organic compounds and their common salts (H, C, N, O, F, Si, P, S, Cl, As, Br, I, Na, Mg, Al, K, Ca, Rb, Cs) are also the most abundant ones. Notable exceptions are B, Li, Se, Sr, and Ba.

M^{+*} is always accompanied by isotope peaks. Their relative abundance depends on the number and kind of the elements present and their natural isotopic distribution. The abundance of $[M+1]^{+*}$ indicates the maximum number of carbon atoms (C_{\max}) according to the following relationship:

$$C_{\max} = 100 \times \text{intensity}([M+1]^{+*}) / \{1.1 \times \text{intensity}(M^{+*})\}$$

$[M+2]^{+*}$ and higher masses indicate the number and kind of elements that have a relatively abundant heavier isotope (such as S, Si, Cl, Br). Note that, in analogy to the calculation of C_{\max} , the ratio of the intensities of $[M+2]^{+*}$ and M^{+*} for a compound with n silicon, o sulfur, p chlorine, or q bromine atoms can be approximated with quite high accuracy from $n \times 3.35\%$, $o \times 4.52\%$, $p \times 31.96\%$, or $q \times 97.28\%$, respectively (see also Chapters 2.5.4 to 2.5.6).

The mass of M^{+*} is always an even number if the molecule contains only elements for which the atomic mass and valence are both even- (C, O, S, Si) or both odd-numbered (H, P, F, Cl, Br, I). In the presence of other elements (e.g., ^{14}N) and isotope labels (e.g., ^{13}C , ^2H), M^{+*} becomes an odd number if they are present in an odd number.

The molecular ion can only form fragment ions of masses that differ from that of M^{+*} by chemically logical values (Δm). In this context, chemically illogical differences are $\Delta m = 3$ (in the absence of $\Delta m = 1$) to $\Delta m = 14$, $\Delta m = 21$ (in the absence of $\Delta m = 1$) to $\Delta m = 24$, $\Delta m = 37, 38$, and all Δm less than the mass of an element of characteristic isotope pattern in cases where the same isotope pattern is not retained in the fragment ion.

M^{+*} must contain all elements (and the maximum number of each) that are shown to be present in the fragment ions.

If ionization is performed by electron impact, M^{+*} is the ion with the lowest appearance potential.

If a pure sample flows into the ion source through a molecular leak, M^{+*} exhibits the same effusion rate as can be determined from the fragment ions. The abundance of M^{+*} is proportional to the sample pressure in the ion source.

For polar compounds, $[M+\text{H}]^{+*}$ is often observed in mass spectra obtained not only with fast atom bombardment and atmospheric pressure chemical ionization but also with electron impact ionization. In this latter case, the abundance of $[M+\text{H}]^{+*}$ changes in proportion to the square of the sample pressure in the ion source.

In the absence of a signal for M^{+*} , the relative molecular weight must have a value that shows a logical and reasonable mass difference, Δm , to all the observed fragment ions.

2.5.9 Homologous Mass Series as Indications of Structural Type

Certain sequences of intensity maxima in the lower mass range and the masses of unique signals are often characteristic of a particular compound type. The intensity distribution of such ion series is in general smooth. Therefore, abrupt changes (maxima and minima) are of structural significance. The ion or ion series most indicative of a particular compound type is set in italics.

Mass values, m/z	Elemental composition	Compound types
12 + 14n	C_nH_{2n-2}	alkenes, monocycloalkanes, alkynes, dienes, cycloalkenes, polycyclic alicyclics, cyclic alcohols
13 + 14n	C_nH_{2n-1}	alkanes, alkenes, <i>monocycloalkanes</i> , alkynes, dienes, cycloalkenes, polycyclic alicyclics, alcohols, alkyl ethers, cyclic alcohols, cyclo-alkanones, aliphatic acids, esters, lactones, thiols, sulfides, glycols, glycol ethers, alkyl chlorides
	$C_nH_{2n-3}O$	cycloalkanones
14 + 14n	C_nH_{2n}	alkanes, alkenes, monocycloalkanes, polycyclic alicyclics, alcohols, alkyl ethers, thiols, sulfides, alkyl chlorides
	$C_nH_{2n-2}O$	cycloalkanones
15 + 14n	C_nH_{2n+1}	<i>alkanes</i> , alkenes, monocycloalkanes, alkynes, dienes, cycloalkenes, polycyclic alicyclics, alkanones, alkanals, glycols, glycol ethers, alkyl chlorides, acid chlorides
	$C_nH_{2n-1}O$	alkanones, alkanals, <i>cyclic alcohols</i> , acid chlorides
16 + 14n	$C_nH_{2n}O$	<i>alkanones, alkanals</i>
	$C_nH_{2n+2}N$	<i>alkyl amines, aliphatic amides</i>
	$C_nH_{2n}NO$	aliphatic amides
17 + 14n	$C_nH_{2n+1}O$	<i>alcohols, alkyl ethers</i> , aliphatic acids, esters, lactones, glycols, glycol ethers
	$C_nH_{2n-1}O_2$	aliphatic acids, esters, lactones
18 + 14n	$C_nH_{2n}O_2$	<i>aliphatic acids, esters, lactones</i>
19 + 14n	$C_nH_{2n+3}O$	alcohols, alkyl ethers
	$C_nH_{2n+1}O_2$	aliphatic acids, esters, lactones
	$C_nH_{2n+1}O_2$	<i>glycols, glycol ethers</i>
	$C_nH_{2n+1}S$	<i>thiols, sulfides</i>
20 + 14n	$C_8H_8 + C_nH_{2n}$	alkylbenzenes
	$C_nH_{2n+2}O_2$	glycols, glycol ethers
	$C_nH_{2n+2}S$	<i>thiols, sulfides</i>

36 **2 Summary Tables**

Mass values m/z	Elemental composition	Compound types
21 + 14n	$C_7H_7 + C_nH_{2n}$	alkylbenzenes
	C_7H_5O	aryl ketones
	$C_nH_{2n}Cl$	<i>alkyl chlorides</i>
	$C_nH_{2n}COCl$	acid chlorides
22 + 14n	$C_6H_6N + C_nH_{2n}$	alkylanilines
	C_nH_{2n-6}	polycyclic alicyclics
23 + 14n	C_nH_{2n-5}	polycyclic alicyclics
24 + 14n	C_nH_{2n-4}	polycyclic alicyclics
25 + 14n	C_nH_{2n-3}	<i>alkynes, dienes, cycloalkenes, polycyclic alicyclics</i>
39, 52±1, 64±1, 76±2, 91±1	$C_nH_{n\pm 1}$	alkylbenzenes, aromatic hydrocarbons, phenols, aryl ethers, aryl ketones

2.5.10 Mass Correlation Table

Note: As long as it makes sense chemically, CH₂, CH₄, CH₃O, and O₂ in the formulae of the second column may be replaced by N, O, P, and S, respectively.

Mass	Ion	Product ion (and neutral particle lost)	Substructure or compound type
1		[M+1] ⁺ , [M-1] ⁻	particularly in FAB spectra, in which M±1 occurs even for moderately basic and acidic compounds, but intensive M ⁺ without M±1 is unusual
7	Li ⁺	[M+7] ⁺ [M-7] ⁻	in FAB spectra in the presence of Li ⁺ (with isotope signal for ⁶ Li) in FAB spectra of organic Li ⁺ salts
12	C ⁺		
13	CH ⁺		
14	CH ₂ ⁺⁺ , N ⁺ , N ₂ ⁺⁺ , CO ⁺⁺		
15	CH ₃ ⁺	[M-15] ⁺	(CH ₃) nonspecific; <i>abundant</i> : methyl, <i>N</i> -ethylamines
16	O ⁺ , NH ₂ ⁺ , O ₂ ⁺⁺	[M-16] ⁺	(CH ₄) methyl (rare) (O) nitro compounds, sulfones, epoxides, <i>N</i> -oxides (NH ₂) primary amines
17	OH ⁺ , NH ₃ ⁺	[M-17] ⁺	(OH) acids (especially aromatic acids), hydroxylamines, <i>N</i> -oxides, nitro com- pounds, sulfoxides, tertiary alcohols (NH ₃) primary amines
18	H ₂ O ⁺ , NH ₄ ⁺	[M-18] ⁺	(H ₂ O) nonspecific; <i>abundant</i> : alcohols, some acids, aldehydes, ketones, lac- tones, cyclic ethers
19	H ₃ O ⁺ , F ⁺	[M-19] ⁺	(F) fluoro compounds
20	HF ⁺ , Ar ⁺⁺ , CH ₂ CN ⁺⁺	[M-20] ⁺	(HF) fluoro compounds

38 2 Summary Tables

Mass	Ion	Product ion (and neutral particle lost)	Substructure or compound type
23	Na^+	$[\text{M}+23]^+$ $[\text{M}-23]^-$	in FAB spectra in the presence of Na^+ ; sometimes strong even if Na^+ is only an impurity in FAB spectra of organic Na^+ salts
24	$\text{C}_2^{+\cdot}$		
25	C_2H^+	$[\text{M}-25]^+$ (C_2H)	terminal acetylenyl
26	$\text{C}_2\text{H}_2^{+\cdot}, \text{CN}^+$	$[\text{M}-26]^{+\cdot}$ (C_2H_2) (CN)	aromatics nitriles
27	$\text{C}_2\text{H}_3^{+\cdot}, \text{HCN}^{+\cdot}$	$[\text{M}-27]^+$ (C_2H_3) $[\text{M}-27]^{+\cdot}$ (HCN)	terminal vinyl, some ethyl esters and <i>N</i> -ethylamides, ethyl phosphates aromatic N, nitriles
28	$\text{C}_2\text{H}_4^{+\cdot}, \text{CO}^{+\cdot}, \text{N}_2^{+\cdot}, \text{HCNH}^+$	$[\text{M}-28]^{+\cdot}$ (C_2H_4) (CO) (N ₂)	nonspecific; <i>abundant</i> : cyclohexenes, ethyl esters, propyl ketones, propyl-substituted aromatics aromatic O, quinones, lactones, lactams, unsaturated cyclic ketones, allyl aldehydes diazo compounds; air (intensity 3.7 times larger than for $\text{O}_2^{+\cdot}$, m/z 32)
29	$\text{C}_2\text{H}_5^+, \text{CHO}^+$	$[\text{M}-29]^+$ (C_2H_5) (CHO)	nonspecific; <i>abundant</i> : ethyl phenols, furans, aldehydes
30	$\text{CH}_2\text{O}^{+\cdot}, \text{CH}_2\text{NH}_2^{+\cdot}, \text{NO}^+, \text{C}_2\text{H}_6^{+\cdot}, \text{BF}^+, \text{N}_2\text{H}_2^{+\cdot}$	$[\text{M}-30]^{+\cdot}$ (C_2H_6) (CH_2O) (NO)	ethylalkanes, polymethyl compounds cyclic ethers, lactones, primary alcohols nitro and nitroso compounds
31	$\text{CH}_3\text{O}^+, \text{CH}_3\text{NH}_2^{+\cdot}, \text{CF}^+, \text{N}_2\text{H}_3^{+\cdot}$	$[\text{M}-31]^+$ (CH_3O) (CH_3NH_2) (N_2H_3)	methyl esters, methyl ethers, primary alcohols O indicator <i>N</i> -methylamines hydrazides
32	$\text{O}_2^{+\cdot}, \text{CH}_3\text{OH}^{+\cdot}, \text{N}_2\text{H}_4^{+\cdot}, \text{S}^+$	$[\text{M}-32]^{+\cdot}$ (O_2) (CH_3OH) (S)	cyclic peroxides; air (intensity 3.7 times smaller than for $\text{N}_2^{+\cdot}$, m/z 28) methyl esters, methyl ethers sulfides (with ³⁴ S isotope signal)
			O indicator

Mass	Ion	Product ion (and neutral particle lost)		Substructure or compound type
33	CH_3OH_2^+ , SH^+ , CH_2F^+	$[\text{M}-33]^+$	(SH)	nonspecific (with isotope signal for ^{34}S)
			($\text{CH}_3 + \text{H}_2\text{O}$)	nonspecific
			(CH_2F)	fluoromethyl
34	SH_2^+	$[\text{M}-34]^+$	(SH_2)	nonspecific (with ^{34}S isotope signal)
			(OH + OH)	S indicator nitro compounds
35	SH_3^+ , Cl^+	$[\text{M}-35]^+$	(Cl)	chloro compounds (with ^{37}Cl isotope signal)
			(OH + H_2O)	O indicator nitro compounds
36	HCl^+ , C_3^+	$[\text{M}-36]^+$	(HCl)	chloro compounds
			($\text{H}_2\text{O} + \text{H}_2\text{O}$)	2 × O indicator
37	C_3H^+ $^{37}\text{Cl}^+$			chloro compounds (with isotope signal for ^{35}Cl)
38	C_3H_2^+			
39	C_3H_3^+ K^+	$[\text{M}-39]^+$	(C_3H_3)	aromatics
		$[\text{M}+39]^+$		in FAB spectra often strong even if K^+ is only an impurity (with isotope signal for ^{41}K)
			$[\text{M}-39]^-$	in FAB spectra of organic K^+ salts
40	C_3H_4^+ , Ar^+ , CH_2CN^+	$[\text{M}-40]^+$	(CH_2CN)	cyanomethyl
41	C_3H_5^+ , CH_3CN^+	$[\text{M}-41]^+$	(C_3H_5)	acyclics (<i>especially</i> polycyclics), alkenes
			(CH_3CN)	2-methyl-N-aromatics, N-methyl-anilines
42	C_3H_6^+ , $\text{C}_2\text{H}_2\text{O}^+$, CON^+ , $\text{C}_2\text{H}_4\text{N}^+$	$[\text{M}-42]^+$	(C_3H_6)	nonspecific; <i>abundant</i> : propyl esters, butyl ketones, butylaromatics, methylcyclohexenes
			($\text{C}_2\text{H}_2\text{O}$)	acetates (<i>especially</i> enol acetates), acetamides, cyclohexenones, α,β -unsaturated ketones
43	C_3H_7^+ , $\text{C}_2\text{H}_3\text{O}^+$, CONH^+	$[\text{M}-43]^+$	(C_3H_7)	nonspecific; <i>abundant</i> : propyl, alicyclics, cycloalkanones, cycloalkylamines, cycloalkanol, butylaromatics
			(CH_3CO)	methyl ketones, acetates, aromatic methyl ethers

2.6 UV/Vis Spectroscopy

UV/Vis Absorption Bands of Various Compound Types (A: alkyl or H; R: alkyl; sh: shoulder)

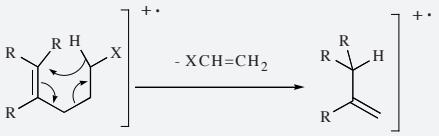

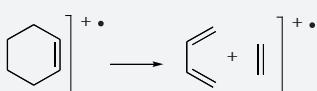

^a longest wavelength absorption maximum

3 Combination Tables

3.1 Alkanes, Cycloalkanes

	Assignment	Range	Comments
¹³C	CH ₃	5–35 ppm	CH ₃ , CH ₂ , CH, and C can be differentiated by multipulse experiments (DEPT, APT), off-resonance decoupling, 2D CH correlation spectra, or based on relaxation times
	CH ₂	5–45 ppm	
	CH	25–60 ppm	
	C	30–60 ppm	Lower shift values in three-membered rings
¹H	CH ₃	0.8–1.2 ppm	
	CH ₂	1.1–1.8 ppm	Lower shift values in three-membered rings
	CH	1.1–1.8 ppm	
IR	CH st	3000–2840 cm ⁻¹	Higher frequency in three-membered rings
	CH ₃ δ as	≈1460 cm ⁻¹	
	CH ₂ δ	≈1460 cm ⁻¹	
	CH ₃ δ sy	≈1380 cm ⁻¹	Doublet for <i>geminal</i> methyl groups
	CH ₂ γ	770–720 cm ⁻¹	In C–(CH ₂) _n –C with n ≥ 4 at ca. 720 cm ⁻¹
MS	Molecular ion m/z 14n + 2		Weak in <i>n</i> -alkanes Very weak in isoalkanes
	Fragments		<i>n</i> -Alkanes: local maxima at 14n + 1, intensity variations: smooth, minimum at [M-15] ⁺ Isoalkanes: local maxima at 14n + 1, intensity distribution: irregular (relative maxima due to fragmentation at branching points with charge retention at the most highly substituted C)
	Rearrange-ments	m/z 14n m/z 14n - 2	<i>n</i> -Alkanes: unspecific Isoalkanes: elimination of alkenes Monocycloalkanes: elimination of alkanes
UV			No absorption above 200 nm

3.2 Alkenes, Cycloalkenes

	Assignment	Range	Comments
13C	C=C C-(C=C)	100–150 ppm 10–60 ppm	Considerable differences between Z and E: 
1H	H-(C=C)	4.5–6.5 ppm	Coupling constants, $ J_{\text{gem}} $ 0–3 Hz J_{cis} 5–12 Hz J_{trans} 12–18 Hz
	CH ₃ -(C=C) CH ₂ -(C=C)	≈1.7 ppm ≈2.0 ppm	Coupling constants, $^3J_{\text{CH}_3-\text{CH}=\text{C}} \approx 7 \text{ Hz}$ $^3J_{\text{CH}_2-\text{CH}=\text{C}} \approx 7 \text{ Hz}$
			In rings, $ J $ smaller:  $n = 2, ^3J \approx 0.5 \text{ Hz}$ $n = 3, ^3J \approx 1.5 \text{ Hz}$ $n = 4, ^3J \approx 4.0 \text{ Hz}$
			Long-range coupling, $^4J_{\text{HC}-\text{C}=\text{CH}}$ 0–2 Hz
IR	H-C(=C) st C=C st H-C(=C) δ oop CH ₂ -(C=C) δ	3100–3000 cm ⁻¹ 1690–1635 cm ⁻¹ 1000–675 cm ⁻¹ 1440 cm ⁻¹	Of variable intensity

	Fragments	m/z 14n - 1 m/z 14n - 3	Local maxima for alkenes Local maxima for monocyclic alkenes Usually, double bonds cannot be localized
	Rearrange- ments		<i>n</i> -Alkenes: unspecific except for: 
			Cyclohexenes: retro-Diels-Alder reaction: 
UV	C=C $\pi \rightarrow \pi^*$ (C=C) ₂ $\pi \rightarrow \pi^*$	< 210 nm (log ε 3–4) 215–280 nm (log ε 3.5–4.5)	Isolated double bonds; for highly substituted double bonds often absorption tail

3.3 Alkynes

	Assignment	Range	Comments
13C	C≡C	65–85 ppm	Coupling constant ${}^2J_{HC\equiv^{13}C} \approx 50$ Hz; often leading to unexpected signs of signals in DEPT spectra and unexpected signals in 2D heteronuclear correlation spectra
1H	C–(C≡C)	0–30 ppm	
	H–(C≡C)	1.5–3.0 ppm	Coupling constants, ${}^4J_{CH-C\equiv CH} \approx 3$ Hz ${}^5J_{CH-C\equiv C-CH} \approx 3$ Hz
	CH ₃ –(C≡C)	≈1.8 ppm	
	CH ₂ –(C≡C)	≈2.2 ppm	
	CH–(C≡C)	≈2.6 ppm	
IR	H–C(≡C) st	3340–3250 cm ⁻¹	Sharp, intensive
	C≡C st	2260–2100 cm ⁻¹	Sometimes very weak
MS	Molecular ion		Weak, in the case of 1-alkynes up to C ₇ often absent
	Fragments		[M-1] ⁺ often significant
	Rearrange- ments		Extensive rearrangements, not very characteristic
UV	C≡C π→π*	< 210 nm (log ε 3.7–4.0)	Isolated double bonds; for highly substituted double bonds often absorption tail

3.4 Aromatic Hydrocarbons

	Assignment	Range	Comments
¹³C	ar C	120–150 ppm	Same ranges for polycyclic aromatic hydrocarbons
	ar CH	110–130 ppm	
	al C–C ar	10–60 ppm	
¹H	H–C ar	6.5–7.5 ppm	In polycyclic aromatic hydrocarbons up to ≈ 9 ppm Coupling constants, $^3J_{\text{ortho}} \approx 7$ Hz $^4J_{\text{meta}} \approx 2$ Hz $^5J_{\text{para}} < 1$ Hz
	CH ₃ –C ar	≈ 2.3 ppm	Often line broadening due to long-range coupling with aromatic protons
	CH ₂ –C ar	≈ 2.6 ppm	
	CH–C ar	≈ 2.9 ppm	
IR	ar C–H st	3080–3030 cm ⁻¹	Often multiple bands, weak
	comb	2000–1650 cm ⁻¹	Very weak
	ar C–C st	≈ 1600 cm ⁻¹ ≈ 1500 cm ⁻¹ ≈ 1450 cm ⁻¹	Of variable intensity, sometimes not all bands observable
	ar C–H δ oop	960–650 cm ⁻¹	Strong, frequently multiple bands
MS	Molecular ion		Strong, often base peak
	Fragments	m/z 39, 50–53, 63–65, 75–78, [M-26] ⁺ , [M-39] ⁺	Often doubly charged fragment ions
	Benzylic cleavage		m/z 91 (90, 92)
	Other typical fragments	 	m/z 127 m/z 152 m/z 165
Rearrange- ments			

UV

Assignment	Range	Comments
	$\approx 200\text{--}210\text{ nm}$ ($\log \epsilon \approx 4$)	In benzene and alkylbenzenes
	$\approx 260\text{ nm}$ ($\log \epsilon \approx 2.4$)	

3.5 Heteroaromatic Compounds**13C**

Assignment	Range	Comments
ar C-X	120–160 ppm	
ar C-C	100–150 ppm	

1H

H-C ar	6–9 ppm	Coupling constants in 6-membered rings similar to those in aromatic hydrocarbons; smaller in 5-membered rings
H-N ar	7–14 ppm	Strongly solvent dependent, generally broad

IR

ar C-H st	3100–3000 cm^{-1}	Often multiple bands, weak
ar N-H st	3500–2800 cm^{-1}	
ar C-C st	$\approx 1600\text{ cm}^{-1}$ $\approx 1500\text{ cm}^{-1}$ $\approx 1450\text{ cm}^{-1}$	Often split, sometimes not all bands observable
ar C-H δ oop	1000–650 cm^{-1}	Often strong, frequently multiple bands

MS

Molecular ion Fragments	m/z 39, 50–53, 63–65, 75–78, $[\text{M}-26]^{+*}$, $[\text{M}-39]^{+}$	Strong, often base peak
	m/z 45 $[\text{CHS}]^{+}$	Often doubly charged fragment ions
	Benzyl-analogous cleavage	S-Heteroaromatics

Rearrange-
ments

Loss of HCN ($\Delta m 27$, *N*-heteroaromatics)
 Loss of CO ($\Delta m 28$, *O*-heteroaromatics)
 Loss of CS ($\Delta m 44$, *S*-heteroaromatics)

	H–C=CBr	5.0–7.0 ppm	
	H–C=CI	5.5–7.5 ppm	
	H–phenyl–hal	7.0–7.6 ppm	Shielding by F in <i>ortho</i> and <i>para</i> positions; small effects for Cl and Br; deshielding by I in <i>ortho</i> , and shielding in <i>meta</i> position
IR	C–F st	1400–1000 cm^{-1}	Strong
	C–Cl st	850–600 cm^{-1}	Strong
	C–Br st	700–500 cm^{-1}	Strong
	C–I st	650–450 cm^{-1}	Strong

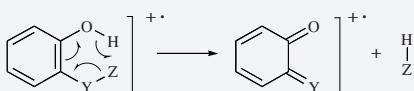

MS

Assignment	Range	Comments
Molecular ion		Often weak for saturated aliphatic halogen compounds, often absent from spectra of aliphatic polyhalogenated compounds
Fragments	m/z 69, 50–53	Characteristic isotope pattern for Cl and Br CF_3 Upon fragmentation of the C–hal bond, the positive charge preferably remains on the alkyl side, and on the halogen side upon fragmentation of the neighboring bond:
Rearrange- ments	$[\text{M}-20]^{+•}$ $[\text{M}-50]^{+•}$ or $[\text{frag}-50]^{+•}$ $[\text{M}-36]^{+•}$	HF elimination CF_2 elimination
UV hal $n \rightarrow \pi^*$	$\leq 280 \text{ nm}$ ($\log \epsilon \approx 2.5$)	HCl elimination For C–I; for C–Br and C–Cl in general only absorption tail, for C–F no absorption

3.7 Oxygen Compounds

3.7.1 Alcohols and Phenols

	Assignment	Range	Comments
¹³C	al C-OH	50–80 ppm	Shift with respect to C-H ≈ 50 ppm
	al C-(C-OH)	10–60 ppm	Hardly any shift with respect to C-(C-CH ₃)
	al C-(C-C-OH)	10–60 ppm	Shift with respect to C-(C-C-CH ₃) ≈ -5 ppm
	ar C-OH	140–155 ppm	Shift with respect to C-H ≈ +25 ppm
	ar C-(C-OH)	100–130 ppm	Shift with respect to C-(C-H): <i>ortho</i> ≈ -13 ppm, <i>meta</i> ≈ +1 ppm, <i>para</i> ≈ -8 ppm
¹H	HO-C al	0.5–6 ppm	Often broad; position and shape strongly depend on experimental conditions
	HO-C ar	4–12 ppm	
	CH ₂ -(OH)	3.5–4.0 ppm	
	CH-(OH)	3.8–4.2 ppm	
	ar CH-(C-OH)	6.5–7.0 ppm	
IR	O-H st	3650–3200 cm ⁻¹	Position and shape depend on the degree of association. Often different bands for H-bonded and free OH
	C-O(H) st	1260–970 cm ⁻¹	Strong
MS	Molecular ion		Aliphatic: weak, often missing in the case of primary and highly branched alcohols; in this case, peaks at highest mass are often due to [M-18] ⁺ or [M-15] ⁺ Aromatic: strong
	Fragments	Aliphatic: m/z 31, 45, 59, ... [M-33] ⁺	Primary: m/z 31 > m/z 45 ≈ m/z 59 Secondary, tertiary: local maxima due to α-cleavage: $\begin{array}{ccc} \text{R}-\overset{\text{+}\cdot}{\underset{\text{H}}{\text{C}}}-\text{OH} & \xrightarrow{-\text{R}\cdot} & \text{R}-\overset{\text{+}\cdot}{\underset{\text{H}}{\text{C}}}=\text{OH} \end{array}$
		Aromatic: [M-28] ⁺ (CO) [M-29] ⁺ (CHO)	CO and CHO elimination also from fragments. H ₂ O elimination ([M-18] ⁺) only with alkyl substituent in <i>ortho</i> position
	Rearrange-ments	Aliphatic: [M-18] ⁺ [M-46] ⁺	Elimination of H ₂ O from M ⁺ followed by alkene elimination; elimination of H ₂ O from products of α-cleavage
		Unsaturated	Vinylcarbinols: spectra similar to those of ketones Allyl alcohols: specific aldehyde elimination:
			$\left[\begin{array}{c} \text{R}_1-\text{CH}=\text{CH}_2-\text{CH}_2-\text{C}(=\text{O})-\text{R}_2 \\ \\ \text{OH} \end{array} \right]^{+\cdot} \xrightarrow{-\text{R}_2\text{CHO}} \left[\begin{array}{c} \text{R}_1-\text{CH}=\text{CH}_2-\text{CH}_2-\text{C}(=\text{O})-\text{R}_2 \\ \\ \text{R} \end{array} \right]^{+\cdot}$

	Assignment	Range	Comments
MS	Aromatic:		<i>Ortho</i> effect with appropriate substituents:  with Y-Z as -CO-OR, C-hal, -O-R, and similar
UV	Aliphatic Aromatic	≈200–210 nm (log ε ≈ 3.8) ≈270 nm (log ε ≈ 2.4)	No absorption above 200 nm In alkaline solution, shift to longer wavelength and increase in intensity due to deprotonation

	Rearrange- ments	m/z 60, 61 [M-18] ^{+•}	Aliphatic acids Aromatic acids <i>Ortho</i> effect with aromatic acids:
			
			for X: CH ₂ , O, N, S, etc.
UV	n → π*	<220 nm (log ε 1–2) ≥193 nm (log ε ≈ 4) ≥230 nm (log ε > 3)	Saturated acids α,β-Unsaturated acids Aromatic acids

3.10.4 Esters and Lactones

	Assignment	Range	Comments
13C	COOR	165–180 ppm	Shift with respect to COOH -5 to -10 ppm
	al C-(COOR)	20–70 ppm	
	al C-(OCOR)	50–100 ppm	Shift with respect to C-(OH) +2 to +10 ppm
	(C)=C-(COOR)	105–160 ppm	
	C=(C-COOR)	105–160 ppm	
	(C)=C-(OCOR)	100–150 ppm	
	C=(C-OCOR)	80–130 ppm	
	ar C-(COOR)	120–150 ppm	
	ar C-(OCOR)	130–160 ppm	
	ar C=(C-OCOR)	105–130 ppm	
1H	al CH-COOR	2.0–2.5 ppm	$\text{CH}_3\text{COOR} \approx 2.0 \text{ ppm}$ $\text{CH}_2\text{COOR} \approx 2.3 \text{ ppm}$ $\text{CH}\text{COOR} \approx 2.5 \text{ ppm}$
	al CH-OCOR	3.5–5.3 ppm	$\text{CH}_3\text{OCOR} \approx 3.5\text{--}3.9 \text{ ppm}$ $\text{CH}_2\text{COOR} \approx 4.0\text{--}4.5 \text{ ppm}$ $\text{CH}\text{COOR} \approx 4.8\text{--}5.3 \text{ ppm}$
	CH=CH-COOR	5.5–8.0 ppm	Shift with respect to CH=CH-H: <i>gem</i> $\approx +0.8 \text{ ppm}$, <i>cis</i> $\approx +1.1 \text{ ppm}$ <i>trans</i> $\approx +0.5 \text{ ppm}$
	CH=CH-OCOR	6.0–8.0 ppm	Shift with respect to CH=CH-H: <i>gem</i> $\approx +2.1 \text{ ppm}$, <i>cis</i> $\approx -0.4 \text{ ppm}$ <i>trans</i> $\approx -0.6 \text{ ppm}$
	ar CH-C-COOR	7.0–8.0 ppm	Shift with respect to CH-(C-H): <i>ortho</i> $\approx +0.7 \text{ ppm}$, <i>meta</i> $\approx +0.1 \text{ ppm}$, <i>para</i> $\approx +0.2 \text{ ppm}$
	ar CH-C-OCOR	6.8–7.5 ppm	Shift with respect to CH-(C-H): <i>ortho</i> $\approx -0.2 \text{ ppm}$, <i>meta</i> $\approx 0 \text{ ppm}$, <i>para</i> $\approx -0.1 \text{ ppm}$
IR	C=O st	1745–1730 cm^{-1}	Strong; range for aliphatic esters Higher wavenumbers for hal-C-COOR, $\text{COO}-\text{C}=\text{C}$, $\text{COO}-\text{C}$ ar, and for small ring lactones Lower wavenumbers for C=C-COOR and ar C-COOR
	C-O st	1330–1050 cm^{-1}	Mostly two bands, at least one of them strong For COO^- , two bands: 1580 and 1420 cm^{-1}

MS

Assignment	Range	Comments
Molecular ion		Aliphatic esters: weak, tendency to protonate Aliphatic lactones: medium to weak, tendency to protonate Aromatic esters and lactones: strong
Fragments	$[M - RO]^+$ $[M - ROCO]^+$	Esters Esters Lactones: loss of α -substituents (attached to ether carbon), decarbonylation, for aromatic lactones also double decarbonylation
Rearrange- ments		Alkene elimination from the alcohol moiety:
		 <p>Elimination of the alcohol side chain with double H transfer (for alcohols with $C_{n>2}$):</p> 
		Alcohol elimination from <i>ortho</i> -substituted aromatic esters:
		
	$[M-18]^{+ \cdot}$	Lactones
UV $n \rightarrow \pi^*$	<220 nm ($\log \epsilon 1-2$) ≥ 193 nm ($\log \epsilon \approx 4$) ≥ 230 nm ($\log \epsilon > 3$)	Aliphatic esters α,β -Unsaturated esters Aromatic esters

3.10.5 Amides and Lactams

	Assignment	Range	Comments
13C	CONR ₂	165–180 ppm	
	al C-(CONR ₂)	20–70 ppm	
	al C-(C-CONR ₂)	5–50 ppm	Shift with respect to C-(C-CH ₃) ≈-6 ppm
	al C-(NCOR)	25–80 ppm	Shift with respect to C-(NH) ≈-1 to -2 ppm
	C=C-(CONR ₂)	105–160 ppm	
	ar C-(CONR ₂)	120–150 ppm	
	ar C-(NCOR)	110–150 ppm	
1H	CONH	5–10 ppm	Frequently broad to very broad; splitting due to H-N-C-H coupling often recognizable only in the CH signal
	al CH-CONR ₂	2.0–2.5 ppm	CH ₃ NCOR ≈2.7–3.0 ppm
	al CH-NCOR	2.7–4.8 ppm	CH ₂ NCOR ≈3.1–3.5 ppm CHNCOR ≈3.8–4.8 ppm
	CH=CH-CONR ₂	5.2–7.5 ppm	Shift with respect to CH=CH-(H): <i>gem</i> ≈+1.4 ppm, <i>cis</i> ≈+1.0 ppm <i>trans</i> ≈+0.5 ppm
	C=CH-NCOR	6.0–8.0 ppm	Shift with respect to CH=CH-(H): <i>gem</i> ≈+2.1 ppm, <i>cis</i> ≈-0.6 ppm
	CH=C-NCOR	4.5–6.0 ppm	<i>trans</i> ≈-0.7 ppm
	ar CH-C(CONR ₂)	7.5–8.5 ppm	Shift with respect to CH-C-(H): <i>ortho</i> ≈+0.6 ppm, <i>meta</i> ≈+0.1 ppm, <i>para</i> ≈+0.2 ppm
	ar CH-C(NCOR)	6.8–7.5 ppm	Shift with respect to CH-C-(H): <i>ortho</i> ≈0 ppm, <i>meta</i> ≈0 ppm, <i>para</i> ≈-0.2 ppm
IR	N-H st	3500–3100 cm ⁻¹	Position and shape depend on the extent of association, often different bands for H-bonded and free NH, always at least two bands for NH ₂
	C=O st (amide I)	1700–1650 cm ⁻¹	Strong; range for amides as well as for δ- and larger lactams, higher wavenumbers for β- and γ-lactams
	N-H δ and N-C=O st sy (amide II)	1630–1510 cm ⁻¹	Often strong, missing in the case of tertiary amides and lactams

MS**UV**

Assignment	Range	Comments
Molecular ion		Aliphatic amides: moderate, tendency to protonate Aromatic amides: strong
Fragments		Amides: cleavage on both sides of the carbonyl group followed by loss of CO; large number of fragments of even mass
Rearrange-ments		Lactams: loss of α -substituent, loss of CO Amides: elimination of the amine moiety, elimination of alkene from the amine or acid moiety in analogy to esters
	[M-18] ⁺	Lactams
n → π*	<220 nm (log ε 1–2)	Aliphatic amides and lactams

Estimation of ^{13}C Chemical Shifts of Aliphatic Compounds (δ in ppm)

The chemical shifts of sp^3 -hybridized carbon atoms can be estimated with the help of an additivity rule using the shift value of methane (-2.3 ppm) and increments (Z) for substituents in α , β , γ , and δ position (see next pages). Some substituents occupy two positions. Thus, the quaternary carbon atom **c** in the example given below is in δ position relative to the carbon atom **a** since the sp^3 -hybridized oxygen of the $\beta\text{-COO}$ group occupies the γ position. This simple linear model needs corrections in case of strong branching of the observed C atom and/or its neighbors (steric corrections, S). Substituents for which such corrections are necessary are those with varying branching, i.e., a varying number of directly bonded H atoms. They are marked with an asterisk (*) in the Table of Increments (next page). Further correction terms are needed if γ substituents are in a sterically fixed position (conformational corrections, K).

The chemical shifts estimated with this additivity rule, in general, differ by less than ca. 4 ppm from the experimental values. Larger discrepancies may be expected for highly branched systems (particularly for quaternary carbon atoms). For carbon atoms bearing several halogen, oxygen, and/or other strongly deshielding substituents, additional correction terms are needed [1]. Without such corrections, deviations can be so large as to render the rule useless.

Example: Estimation of chemical shifts for *N*-(*tert*-butoxycarbonyl)alanine

tertiary (CH)	0.0	-3.7	-8.5	-10.0
quaternary (C)	-1.5	-8.0	-10.0	-12.5

^a To be applied to each of the neighboring atoms that has an unspecified number of non-hydrogen substituents (marked with an asterisk (*) in the Table of Increments, Z_i).

Conformational Corrections, K_k , for γ Substituents

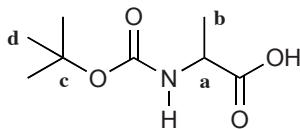

Conformation	K
synperiplanar (eclipsed)	-4.0
synclinal (gauche)	-1.0
anticlinal	0.0
antiperiplanar (anti)	2.0
not fixed	0.0

One can also use the chemical shifts of a reference compound as the base value if its structure is closely related to that assumed for the unknown. The increments corresponding to the structural elements missing in the reference compound are then added to the base value, while those of structural elements present in the reference but absent in the unknown are subtracted (see example on next page).

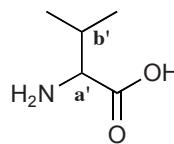

Example: Estimation of the chemical shifts for the carbon atoms **a** and **b** in *N*-(*tert*-butoxycarbonyl)alanine using the chemical shifts of valine as base values (**a'**, **b'**):

Target:

4.1.2 Coupling Constants

$^{13}\text{C}-^1\text{H}$ Coupling Constants

Coupling through one bond ($^1J_{\text{CH}}$ in Hz)

The $^{13}\text{C}-^1\text{H}$ coupling constant of 125 Hz in methane increases in the presence of electronegative substituents and can be estimated by using the following additivity rule:

$$J_{\text{CH}Z_1Z_2Z_3} = 125.0 + \sum_i Z_i$$

Substituent	Increment Z_i	Substituent	Increment Z_i
-H	0.0	-Br	27.0
-CH ₃	1.0	-I	26.0
-C(CH ₃) ₃	-3.0	-OH	18.0
-CH ₂ Cl	3.0	-O-phenyl	18.0
-CH ₂ Br	3.0	-NH ₂	8.0
-CH ₂ I	7.0	-NHCH ₃	7.0
-CHCl ₂	6.0	-N(CH ₃) ₂	6.0
-CCl ₃	9.0	-C≡N	11.0
-C≡C	7.0	-S(O)CH ₃	13.0
-phenyl	1.0	-CHO	2.0
-F	24.0	-COCH ₃	-1.0
-Cl	27.0	-COOH	5.5

Example: Estimation of $^{13}\text{C}-^1\text{H}$ coupling constant of CHCl₃:
 $J = 125.0 + 3 \times 27.0 = 206.0$ Hz (exp: 209.0 Hz).

Coupling through more than one bond ($|J_{CH}|$ in Hz)

The coupling constants can be estimated from the corresponding ^1H - ^1H coupling constants [2]: $J_{\text{CH}} \approx 0.62 J_{\text{HH}}$

Typical values:

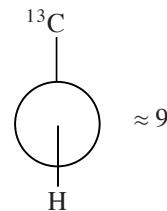

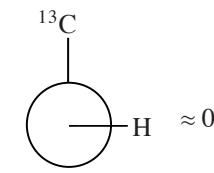

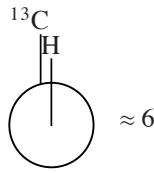

$$^2J_{\text{CH}} \quad 1-6$$

$$^3J_{\text{CH}} \quad 0-10$$

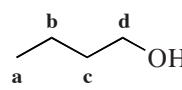

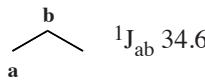

Examples:

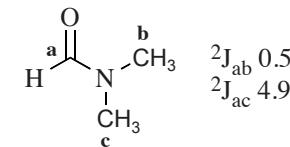

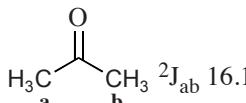

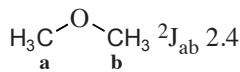

The ^{13}C - ^1H coupling constants for coupling across three bonds depend on the dihedral angle in the same way as the vicinal ^1H - ^1H coupling constants (see Chapter 5.1.2):

^{13}C - ^{13}C Coupling Constants ($|J_{\text{CCl}}$ in Hz)

$$\begin{array}{ll} ^2J_{\text{ac}} & 4.6 \\ ^3J_{\text{ad}} & 4.6 \\ ^2J_{\text{bd}} & <1 \end{array}$$

The ^{13}C - ^{13}C coupling constants for coupling over three bonds depend on the dihedral angle in the same way as the vicinal ^1H - ^1H (see Chapter 5.1.2) and ^{13}C - ^1H coupling constants. Maximum values of ca. 4–6 Hz are observed for dihedral angles of 0° and 180° and minimal values around 0 Hz at 90° .

4.2 Alkenes

4.2.1 Chemical Shifts

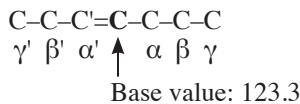

^{13}C Chemical Shifts (δ in ppm)

C=C

The ^{13}C chemical shifts of the carbons of C=C double bonds typically range from ca. 80–160 ppm; a wider range of 40–210 ppm is observed with O and N substituents. In unsaturated *acyclic hydrocarbons*, they can be predicted with high accuracy (see below). To estimate the ^{13}C chemical shifts in all other *substituted alkenes*, one can use the substituent effects listed for chemical shifts in vinyl groups. However, since no configuration-dependent parameters are available, the values thus estimated are less accurate than those for unsaturated acyclic hydrocarbons.

The ^{13}C chemical shifts of sp^3 -hybridized carbon atoms in the vicinity of double bonds can be estimated using the additivity rule given in Chapter 4.1.1. The conformational correction factors, K, for γ substituents of *cis*- vs. *trans*-disubstituted alkenes differ by 6 ppm because the relative position of these substituents is fixed by the double bond.

Estimation of the ^{13}C Chemical Shifts of sp^2 -Hybridized Carbon Atoms in Unsaturated Acyclic Hydrocarbons (δ in ppm)

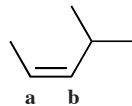

Increments for C substituents:

at C atom under consideration (C)		at neighboring C atom (C')	
α	10.6	α'	-7.9
β	4.9	β'	-1.8
γ	-1.5	γ'	1.5

Steric corrections:

- | | |
|--|------|
| • for each pair of <i>cis</i> - α,α' -substituents | -1.1 |
| • for a pair of geminal α,α -substituents | -4.8 |
| • for a pair of geminal α',α' -substituents | 2.5 |
| • if one or more β -substituents are present | 2.3 |

Example: Estimation of chemical shifts of *cis*-4-methyl-2-pentene

	-I	-38.1	7.0		-Si(CH ₃) ₃	16.9	6.7
					-SiCl ₃	8.7	16.1

* Estimated values

The values listed on the preceding page can also be used to estimate the ^{13}C chemical shifts of sp^2 -hybridized carbon atoms in alkenes with more than one substituent (note that the *cis/trans* configuration is not taken into account):

$$\delta_{\text{C}_i} = 123.3 + \sum Z_i$$

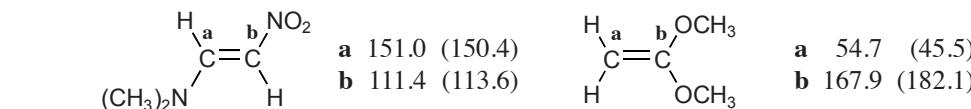

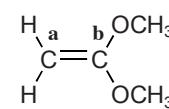

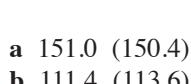

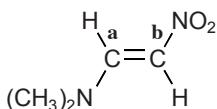

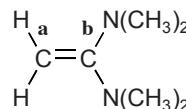

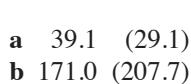

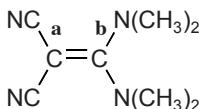

C=C

Example: Estimation of chemical shifts of 1-bromo-1-propene

a	base value	123.3	b	base value	123.3
Z ₁ (Br)	-8.6		Z ₂ (Br)	-0.9	
Z ₂ (CH ₃)	-7.4		Z ₁ (CH ₃)	12.9	
estimated	107.3		estimated	135.3	
exp	108.9 (<i>cis</i>)		exp	129.4 (<i>cis</i>)	
	104.7 (<i>trans</i>)			132.7 (<i>trans</i>)	

The following examples show some larger deviations between measured and estimated (in parentheses) chemical shifts. This is usually to be expected when several substituents are present that strongly interact with the π electrons of the double bond:

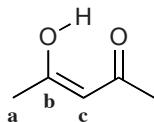

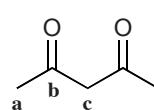

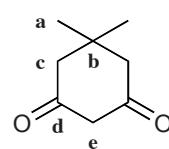

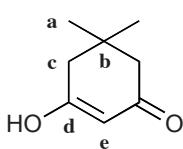

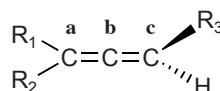

^{13}C Chemical Shifts of *cis*- and *trans*-1,2-Disubstituted Alkenes (δ in ppm)

Substituent R		
$-\text{CH}_3$	123.3	124.5
$-\text{CH}_2\text{CH}_3$	131.2	131.3
$-\text{Cl}$	118.1	119.9
$-\text{Br}$	116.4	109.4

Additivity rule for estimating the chemical shifts of *sp*-hybridized carbon atoms in alkynes: see [1].

4.3.2 Coupling Constants

^{13}C - ^1H Coupling Constants ($|J_{\text{CH}}$ in Hz) [2]

With acetylenes, the results of multipulse experiments (such as DEPT, INEPT, SEFT, or APT) to determine the number of protons attached to the carbon atoms must be interpreted with care. As a consequence of the unusually large ^{13}C - ^1H coupling constants through one and two bonds, the sign of the signals may be opposite to the expected one. For the same reasons, unexpected signals may occur in two-dimensional heteronuclear correlation spectra (HSQC, HMBC).

^{13}C - ^{13}C Coupling Constants ($|J_{CC}|$ in Hz)

Estimation of ^{13}C Chemical Shifts of Alicyclic Compounds (δ in ppm)

The ^{13}C chemical shift of the parent compound (e.g., 22.9 for cyclobutane, 26.0 for cyclopentane, and 27.1 ppm for cyclohexane) and the same increments as for alkanes (see Chapter 4.1) can be used to estimate the chemical shifts of sp^3 -hybridized carbon atoms of alicyclic compounds. Appropriate use of the conformational correction terms, K, is especially important with axial and equatorial substituents in cyclohexanes. The additivity rule is, however, not suitable for estimating chemical shifts of substituted cyclopropanes.

Estimation of ^{13}C Chemical Shifts of Multiply Substituted Benzenes and Naphthalenes (δ in ppm)

The ^{13}C chemical shifts of multiply substituted benzenes and naphthalenes (see next pages) can be estimated using the substituent effects in the corresponding monosubstituted hydrocarbons.

Example: Estimation of the chemical shifts for 3,5-dimethylnitrobenzene

C-1	base value	128.5
	$Z_1(\text{NO}_2)$	19.9
	$2 Z_3(\text{CH}_3)$	-0.2
	estimated	148.2
	exp	148.5

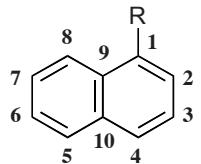

C-2	base value	128.5
	$Z_2(\text{NO}_2)$	-4.9
	$Z_2(\text{CH}_3)$	0.7
	$Z_4(\text{CH}_3)$	-3.0
	estimated	121.3
	exp	121.7

C-3	base value	128.5
	$Z_1(\text{CH}_3)$	9.2
	$Z_3(\text{CH}_3)$	-0.1
	$Z_3(\text{NO}_2)$	0.9
	estimated	138.5
	exp	139.6

C-4	base value	128.5
	$2 Z_2(\text{CH}_3)$	1.4
	$Z_4(\text{NO}_2)$	6.1
	estimated	136.0
	exp	136.2

Larger discrepancies between estimated and experimental values are to be expected if the substituents are *ortho* to each other or if strongly electron-donating and electron-accepting groups occur simultaneously.

Effect of Substituents in Position 1 on ¹³C Chemical Shifts of Monosubstituted Naphthalenes (δ in ppm)

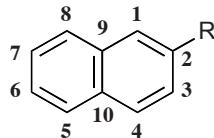

for R: H $\delta_{C_1} = 128.0$
 $\delta_{C_2} = 125.9$
 $\delta_{C_9} = 133.6$

**Estimation of ^{13}C Chemical Shifts of Multiply Substituted Pyridines
(δ in ppm)**

The ^{13}C chemical shifts in multiply substituted pyridines can be estimated using the substituent effects in the monosubstituted parent compound.

Example: Estimation of the chemical shifts for 2-amino-5-methylpyridine

C-2	base value	149.8
	2-NH ₂	8.4
	5-CH ₃	-2.3
	estimated	155.9
	exp	156.9

C-3	base value	123.7
	2-NH ₂	-15.1
	5-CH ₃	-0.9
	estimated	107.7
	exp	108.4

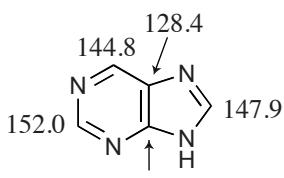

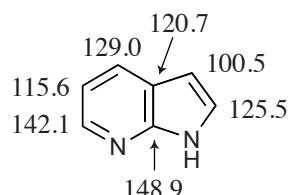

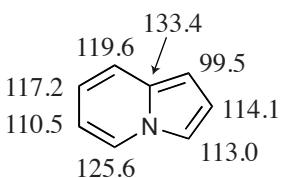

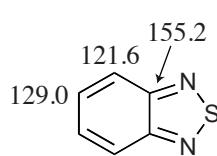

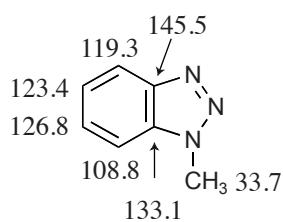

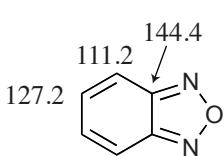

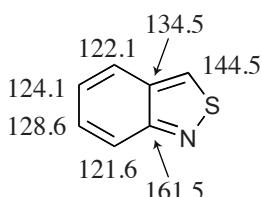

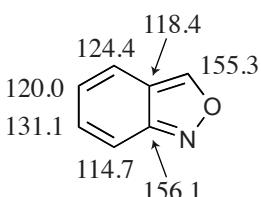

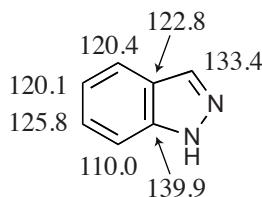

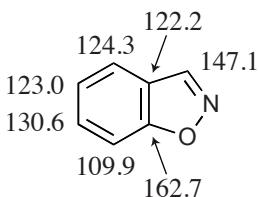

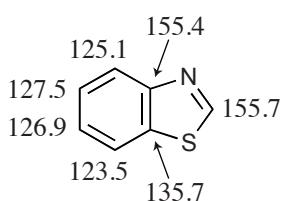

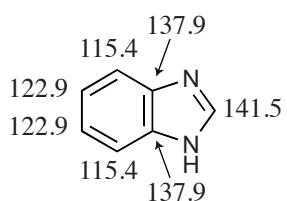

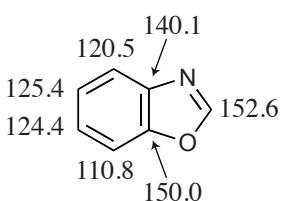

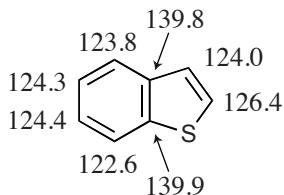

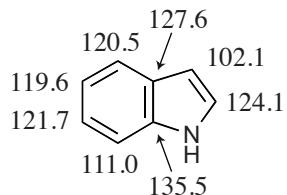

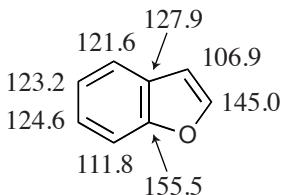

C-4	base value	135.9
	2-NH ₂	1.8
	5-CH ₃	0.0
	estimated	137.7
	exp	138.6

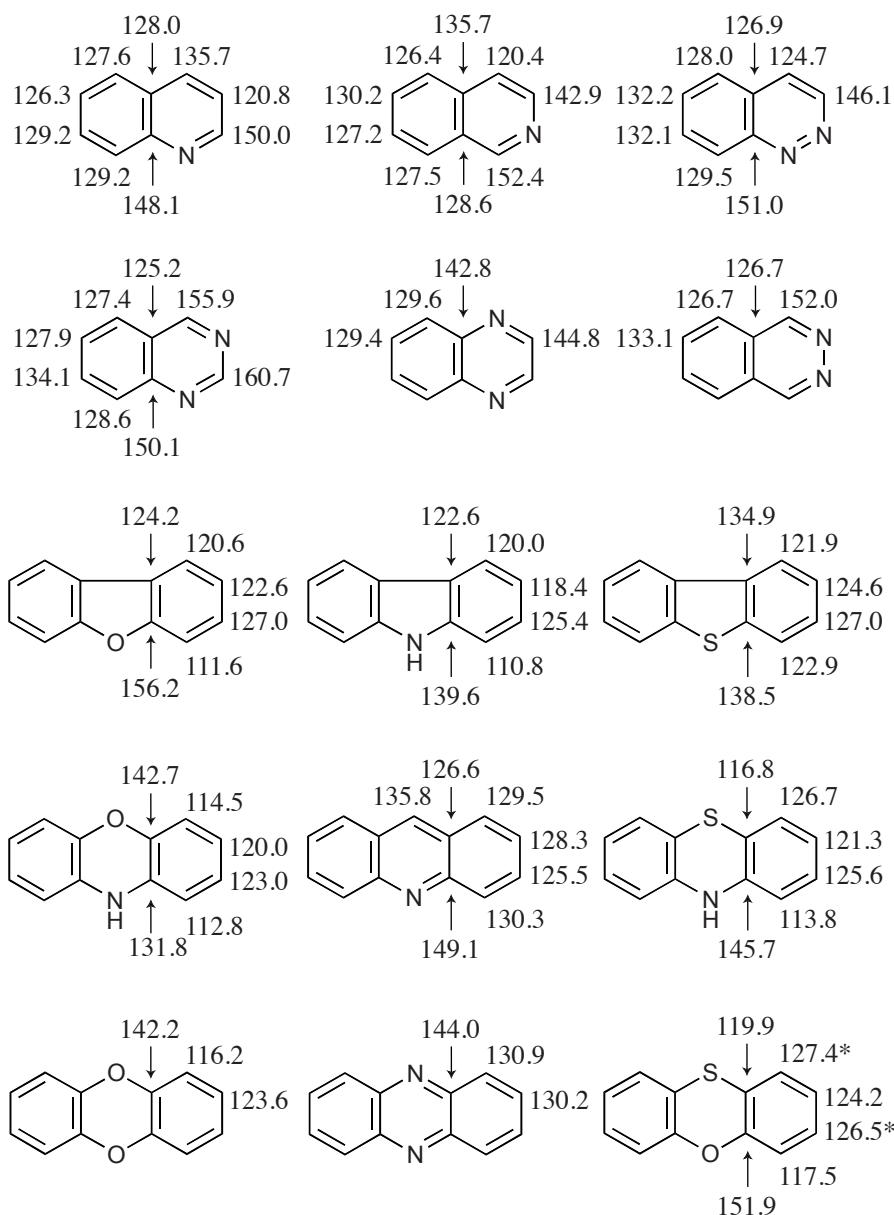

C-5	base value	123.7
	2-NH ₂	-9.7
	5-CH ₃	8.9
	estimated	122.9
	exp	122.5

C-6	base value	149.8
	2-NH ₂	-1.6
	5-CH ₃	1.3
	estimated	149.5
	exp	147.6

Larger discrepancies between estimated and experimental values are to be expected if the substituents are *ortho* to each other and if strongly electron-donating and -accepting groups occur simultaneously. Also, tautomerization and zwitterion formation have large effects on ^{13}C chemical shifts.

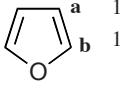

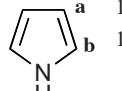

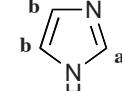

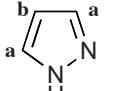

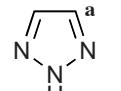

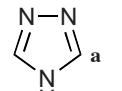

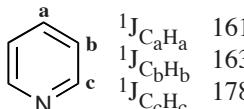

^{13}C Chemical Shifts of Condensed Heteroaromatics (δ in ppm)

* Assignment uncertain

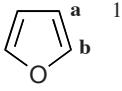

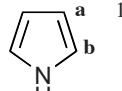

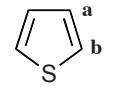

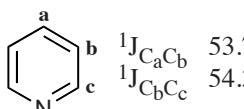

4.6.2 Coupling Constants

¹³C-¹H Coupling Constants ($|^1J|$ in Hz)

	${}^1J_{C_aH_a}$	175		${}^1J_{C_aH_a}$	169		${}^1J_{C_aH_a}$	206
	${}^1J_{C_bH_b}$	202		${}^1J_{C_bH_b}$	183		${}^1J_{C_bH_b}$	189
	${}^1J_{C_aH_a}$	186		${}^1J_{C_aH_a}$	194		${}^1J_{C_aH_a}$	209
	${}^1J_{C_bH_b}$	177						
	${}^1J_{C_aH_a}$	161						
	${}^1J_{C_bH_b}$	163						
	${}^1J_{C_cH_c}$	178						

¹³C-¹³C Coupling Constants ($|^1J|$ in Hz)

	${}^1J_{C_aC_b}$	69.1		${}^1J_{C_aC_b}$	65.6		${}^1J_{C_aC_b}$	64.2
	${}^1J_{C_aC_b}$	53.7						
	${}^1J_{C_bC_c}$	54.3						

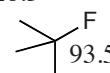

4.7 Halogen Compounds

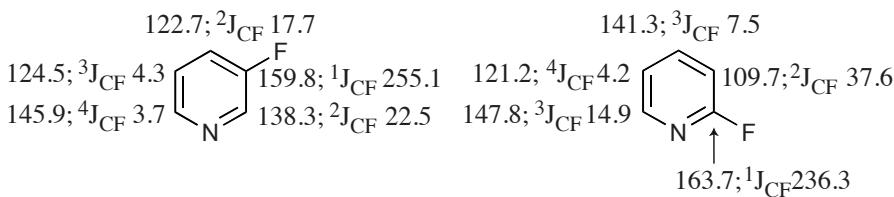

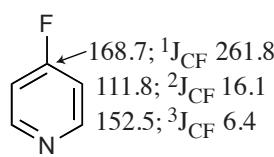

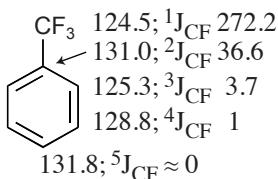

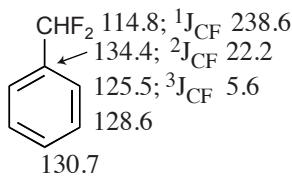

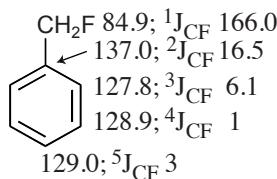

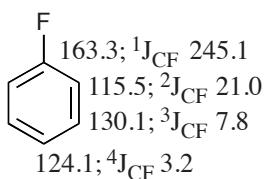

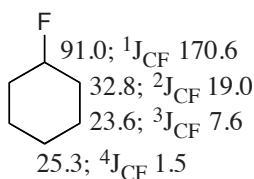

The additivity rules for estimating the ^{13}C chemical shifts of various skeletons can be applied to those haloalkanes that do not have more than one halogen atom at a given carbon atom. In all other cases, the simple linear models fail but correction terms for non-additivity are available for halomethanes and derivatives (see [1, 2]).

4.7.1 Fluoro Compounds

^{19}F (natural abundance 100%) has a spin quantum number I of 1/2. The signals of carbon atoms up to a distance of about four bonds are split by coupling to ^{19}F .

4.9 Nitrogen Compounds

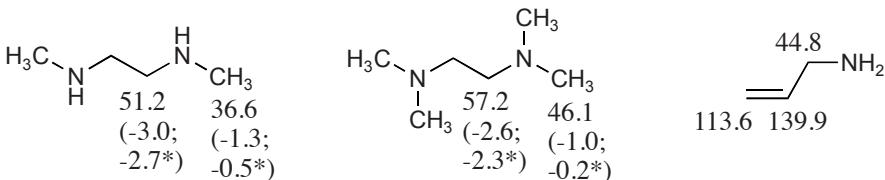

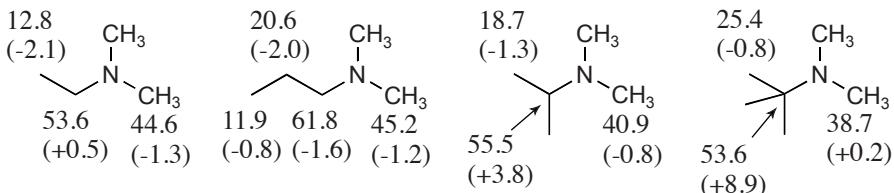

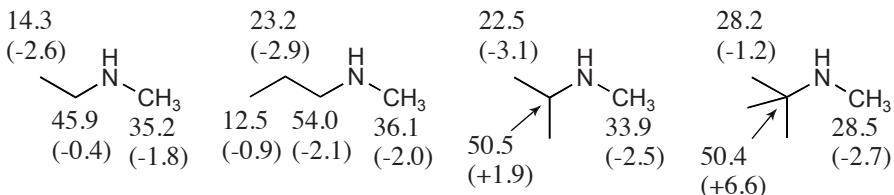

4.9.1 Amines

^{13}C Chemical Shifts of Amines and Ammonium Salts (δ in ppm)

The protonation of amines causes a shielding of the carbon atoms in the vicinity of the nitrogen. This shielding amounts to -2 ppm for an α carbon atom, -3 to -4 for a β carbon, and -0.5 to -1.0 ppm for a γ carbon. The most frequent exceptions occur in branched systems: Tertiary and quaternary carbon atoms in the α -position are generally deshielded by protonation of the nitrogen ($\Delta\delta = +0.5$ to +9 ppm) [1]. In the following, shifts induced by protonation ($\delta_{\text{amine hydrochloride}} - \delta_{\text{amine}}$, measured in D_2O) are given in parentheses.

^{13}C Chemical Shifts of Sulfurous and Sulfuric Acid Derivatives (δ in ppm)

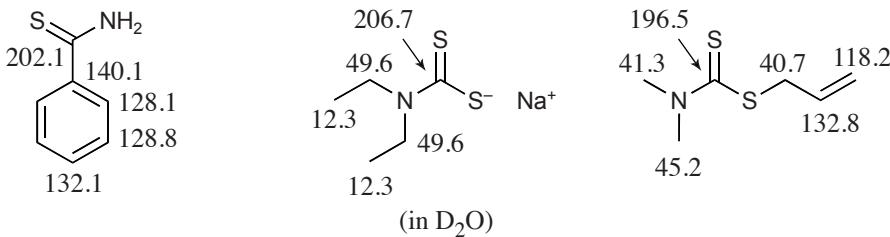

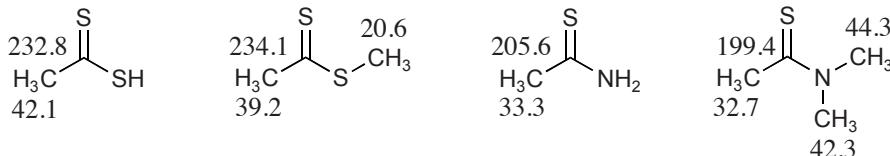

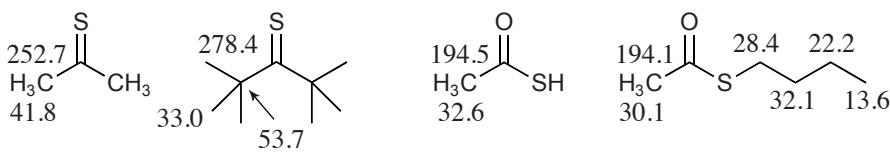

4.10.7 Sulfur-Containing Carbonyl Derivatives

^{13}C Chemical Shifts (δ in ppm)

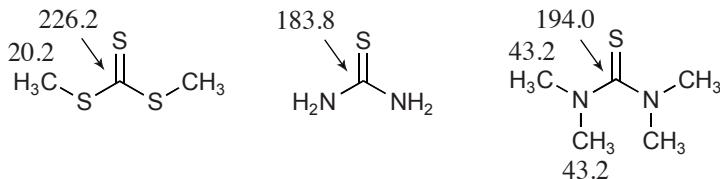

The ^{13}C chemical shifts of thiocarbonyl groups are higher by about 30 ppm than those of the corresponding carbonyl groups:

$$\delta_{\text{C=S}} \approx 1.5 \times \delta_{\text{C=O}} - 57.5$$

Carbonyl groups of thiocarboxylic acids and their esters are deshielded by about 20 ppm with respect to the corresponding oxygen compounds.

4.14.2 ^{13}C NMR Spectra of Secondary Reference Compounds

Chemical shifts in ^{13}C NMR spectra are usually reported relative to the peak position of tetramethylsilane (TMS), which is added as an internal reference. If TMS is not sufficiently soluble in the sample, the use of a capillary with TMS as external reference is recommended. In this case, owing to the difference in volume susceptibilities, the local magnetic fields in the solvent and reference are different. Therefore, the position of the reference must be corrected. For a D_2O solution in a cylindrical sample with TMS in a capillary, the correction amounts to +0.68 and -0.34 ppm for superconducting and electromagnets, respectively. These values must be subtracted from the ^{13}C chemical shifts relative to the external TMS signal if its position is set to 0.00 ppm. Alternatively, secondary references with $(\text{CH}_3)_3\text{SiCH}_2$ groups may be used. The following spectra of two secondary reference compounds in D_2O were measured at 125 MHz with a superconducting magnet and TMS as external reference. Chemical shifts are reported in ppm relative to TMS upon correction for the difference in the volume susceptibilities of D_2O . As a result, the peak for the external TMS appears at 0.68 ppm.

3-(Trimethylsilyl)-1-propanesulfonic acid sodium salt (sodium 4,4-dimethyl-4-silapentane-1-sulfonate; DSS)

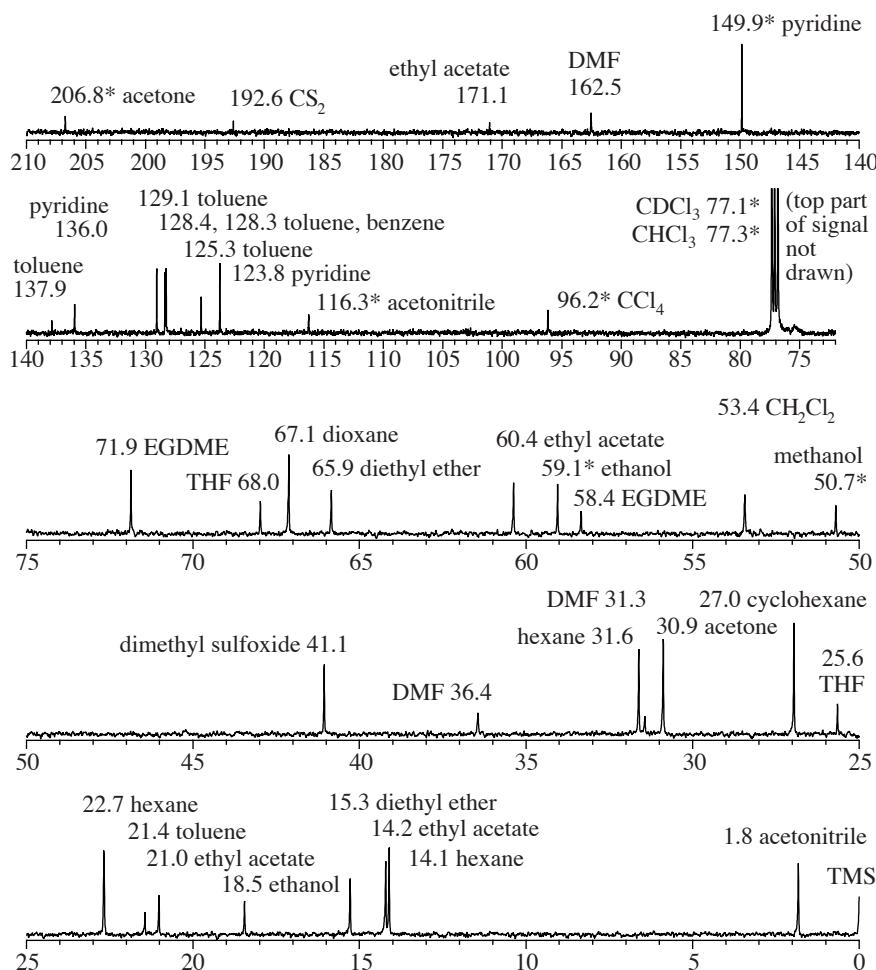

2,2,3,3-D₄-3-(Trimethylsilyl)-propionic acid sodium salt

4.14.3 ^{13}C NMR Spectrum of a Mixture of Common Nondeuterated Solvents

The broad-band-decoupled ^{13}C NMR spectrum (125 MHz, δ in ppm relative to TMS) of a CDCl_3 sample with 20 common solvents (0.05–0.4 vol%) shown below serves as a guide to identify possible solvent impurities. Chemical shifts of signals marked with an asterisk (*) may change up to a few ppm if the sample contains solutes having functional groups that can form hydrogen bonds.

DMF: dimethyl formamide; THF: tetrahydrofuran; EGDME: ethylene glycol dimethyl ether.

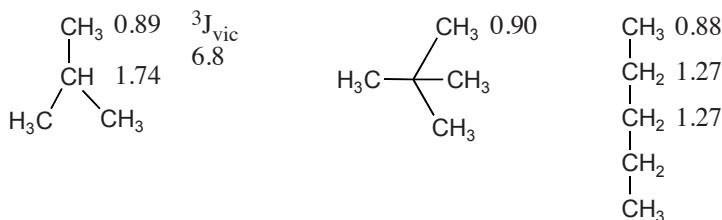

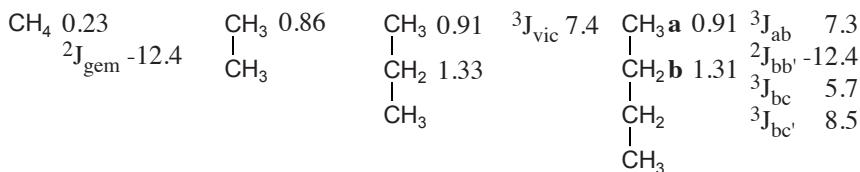

5 ^1H NMR Spectroscopy

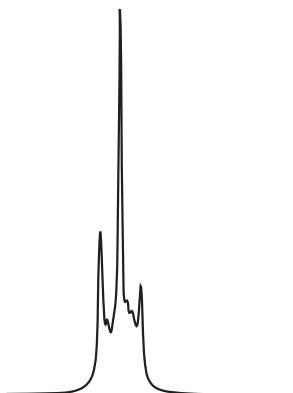

5.1 Alkanes

5.1.1 Chemical Shifts

^1H Chemical Shifts and Coupling Constants (δ in ppm, J in Hz)

In long-chain alkanes, the methyl groups at δ ca. 0.8 ppm typically show distorted triplets due to second-order effects:

¹H Chemical Shifts of Aromatically Substituted Alkanes (δ in ppm)

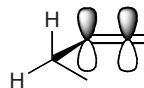

5.1.2 Coupling Constants

Geminal Coupling Constants (2J in Hz)

$$^2J_{\text{HCH}} \text{ -8 to -18}$$

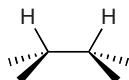

Electronegative substituents cause a decrease in $|J|_{\text{gem}}$ while a double or triple bond next to the CH_2 group causes an increase. The latter effect is strongest if one of the C–H bonds is parallel to the π orbitals:

Influence of Substituents on the Geminal Coupling Constant

Compound	J_{gem}	Compound	J_{gem}
CH_4	-12.4	CH_3COCH_3	-14.9
CH_3Cl	-10.8	CH_3COOH	-14.5
CH_2Cl_2	-7.5	CH_3CN	-16.9
CH_3OH	-10.8	$\text{CH}_2(\text{CN})_2$	-20.3
	-14.3		-18.5

Vicinal Coupling Constants (3J in Hz)

conformation not fixed: $^3J_{\text{HCCH}} \approx 7$
fixed: $^3J_{\text{HCCH}} \approx 0\text{--}18$

Influence of Substituents on the Vicinal Coupling Constant

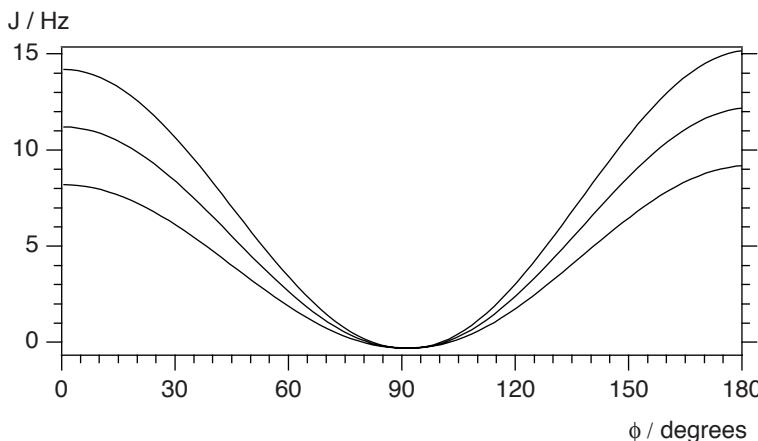

Compound	J_{vic}	Compound	J_{vic}	Compound	J_{vic}
CH_3CHF_2	4.5	$\text{CH}_3\text{CH}_2\text{OH}$	6.9	$\text{CH}_3\text{CH}_2\text{CN}$	7.6
CH_3CHCl_2	6.1	$(\text{CH}_3\text{CH}_2)_3\text{O}^+\text{BF}_4^-$	7.2	$(\text{CH}_3\text{CH}_2)_2\text{S}$	7.4
$\text{CH}_3\text{CH}_2\text{F}$	6.9	$(\text{CH}_3\text{CH}_2)_3\text{N}$	7.1	$(\text{CH}_3\text{CH}_2)_4\text{Si}$	8.0
$\text{CH}_3\text{CH}_2\text{Cl}$	7.2	$(\text{CH}_3\text{CH}_2)_4\text{N}^+\text{I}^-$	7.3	$\text{CH}_3\text{CH}_2\text{Li}$	8.4

Vicinal coupling constants strongly depend on the dihedral angle, ϕ (Karplus equation):

$$\begin{aligned} {}^3J &= J^0 \cos^2 \phi - 0.3 & 0^\circ \leq \phi \leq 90^\circ \\ {}^3J &= J^{180} \cos^2 \phi - 0.3 & 90^\circ \leq \phi \leq 180^\circ \end{aligned}$$

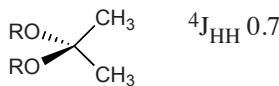

The same relationship between torsional angle and vicinal coupling constant holds for substituted alkanes if appropriate values are used for J^0 and J^{180} . These limiting values depend on the electronegativity and orientation of substituents, the hybridization of carbon atoms, bond lengths, and bond angles.

Long-Range Coupling Constants ($|J|$ in Hz)

Coupling constants through more than three bonds (long-range coupling) in alkanes are generally much smaller than 1 Hz and, thus, not visible in routine 1D NMR spectra. They are, however, much larger than 1 Hz for fixed conformations (e.g., in condensed alicyclic systems, see Chapter 5.4) and in unsaturated compounds (see Chapter 5.2). They are also significant when electronegative substituents are present between the coupling partners, as e.g.:

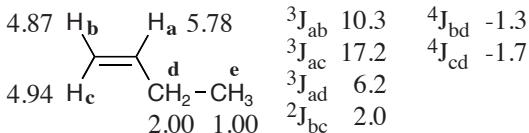

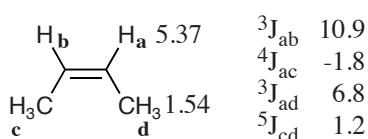

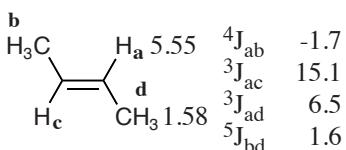

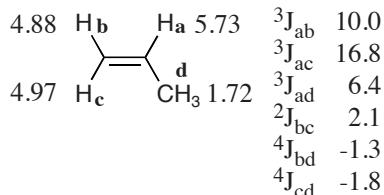

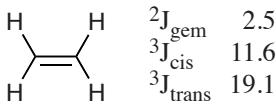

5.2 Alkenes

5.2.1 Substituted Ethylenes

^1H Chemical Shifts and Coupling Constants (δ in ppm, J in Hz)

C=C

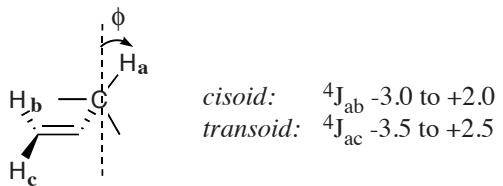

Geminal and Vicinal Couplings of Alkenes (J in Hz)

The values of the coupling constants strongly depend on the electronegativity of the substituents (see Table on pp 166, 167). They decrease with increasing electronegativity and number of electronegative substituents. The same trend holds for the signed values of geminal coupling constants but not for the absolute values because J_{gem} can be positive or negative. Although the total ranges of cis and trans vicinal coupling constants overlap, $J_{\text{trans}} > J_{\text{cis}}$ always holds for given substituents.

Typical ranges:	J_{gem}	-4 to 4
	J_{cis}	4 to 12
	J_{trans}	14 to 19

Coupling Over More than Three Bonds in Alkenes (Long-Range Coupling, J in Hz)

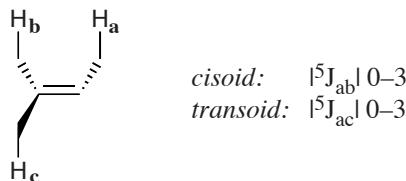

Allylic Coupling

In acyclic systems, the coupling constants range from ca. -0.8 to -1.8 Hz and, usually, $|J|_{\text{cisoid}}$ is larger than $|J|_{\text{transoid}}$. The magnitudes of the coupling constants depend on the conformation. Largest absolute values are observed if the C–H bond of the substituents overlaps with the π electrons of the double bond ($\phi = 0$ or 180°):

ϕ	${}^4J_{ab}$	${}^4J_{ac}$
0°	-3.0	-3.5
90°	+1.8	+2.2
180°	-3.0	-3.5
270°	0.0	0.8

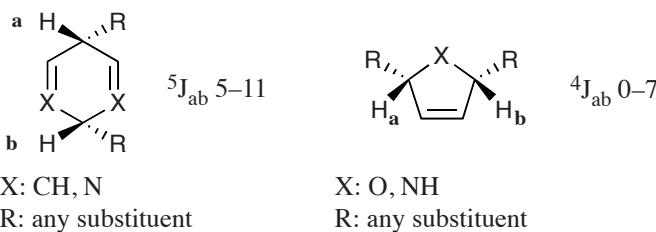

Homoallylic Coupling

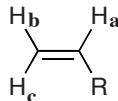

The values of homoallylic coupling constants between methyl groups and of allylic ones are comparable:

$${}^5J_{\text{H}_3\text{C}-\text{C}=\text{C}-\text{CH}_3} \approx {}^4J_{\text{H}-\text{C}=\text{C}-\text{CH}_3}$$

In acyclic systems, $|J|_{\text{cisoid}} < |J|_{\text{transoid}}$ usually holds. Large homoallylic coupling constants are occasionally observed in cyclic systems with fixed conformation between the protons:

$^1\text{H}, ^1\text{H}$ Coupling Constants of Substituted Alkynes (J in Hz)

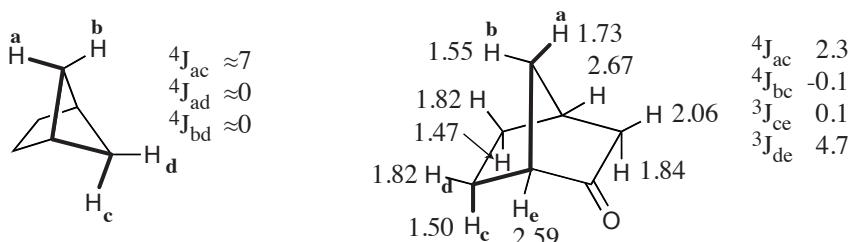

5.4 Alicyclics

¹H Chemical Shifts and Coupling Constants of Saturated Alicyclic Hydrocarbons (δ in ppm, J in Hz)

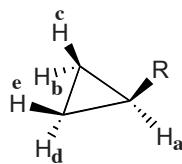

In condensed alicyclics, couplings over four bonds are often observed. Such long-range couplings are particularly large if the arrangement of the bonds between the two protons is W-shaped (cf. J_{ac} vs. J_{ad} and J_{bd} below left and J_{ac} vs. J_{bc} below right). Owing to the rigid arrangement, vicinal coupling constants (3J) may assume unusually small values when the torsional angles are close to 90° (J_{ce} below right).

 $^3J_{\text{ef}}$ ≈9

Weak long-range couplings between aromatic protons and aliphatic substituents are usually not resolved but lead to a characteristic broadening of the corresponding lines.

5.8 Alcohols, Ethers, and Related Compounds

5.8.1 Alcohols

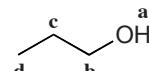

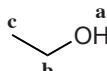

^1H Chemical Shifts and Coupling Constants (δ in ppm, J in Hz)

Aliphatic and alicyclic alcohols: $\delta_{\text{OH}} = 0.5\text{--}3.0$ (in DMSO: 4–6) ppm

Phenols: $\delta_{\text{OH}} = 4.0\text{--}8.0$ (in DMSO: 8–12) ppm

Hydrogen bonds strongly deshield hydroxyl protons. The position of the signal may depend heavily on the experimental conditions including the concentration of the sample. If a compound contains several kinds of hydroxyl protons ($-\text{OH}$, $-\text{COOH}$, H_2O), in general only one signal at an average position is seen because of rapid exchange. In dimethyl sulfoxide (DMSO) as solvent, this exchange in most cases is so slow that isolated signals are obtained. In this case, the chemical shifts of hydroxyl protons are characteristic. However, if the sample contains strong acids or amine bases, the exchange rate increases and, also in DMSO, a single signal at an average position is observed. Frequently, intermediate exchange rates lead to very broad signals extending over several ppm and, therefore, sometimes not discernible in routine spectra.

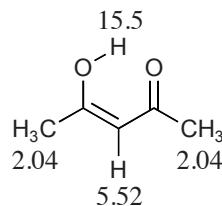

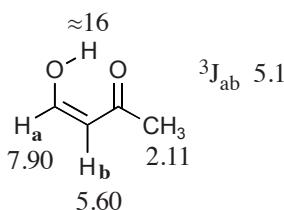

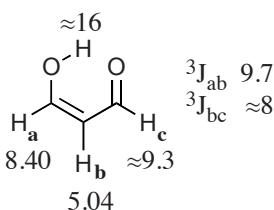

As a consequence of fast intermolecular exchange of the hydroxyl protons, their coupling with the protons on the adjacent carbon atoms is usually not observed. However, in very pure (acid-free) solutions or in DMSO, the exchange is sufficiently slow so that the $\text{H}-\text{O}-\text{C}-\text{H}$ couplings become visible. Their dependence on the conformation is analogous to that shown by the $\text{H}-\text{C}-\text{C}-\text{H}$ couplings (Chapter 5.1.2). In case of fast rotation: ${}^3J_{\text{HOCH}} \approx 5$ Hz. In cyclohexanols, the vicinal coupling constants for axial hydroxyl protons (3.0–4.2 Hz) are lower than those of equatorial ones (4.2–5.7 Hz).

O

5.9 Nitrogen Compounds

5.9.1 Amines

Amine and Ammonium Protons (δ in ppm, $|J|$ in Hz)

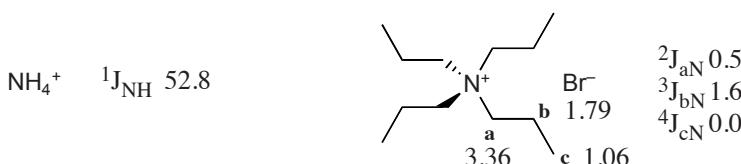

Chemical shifts of amine protons lie around 0.5–6 ppm depending on solvent, concentration, and hydrogen bonding. Those of ammonium protons are found between ca. 7 and 12 ppm. Neighboring H bond acceptors lead to deshielding in all cases.

			in CDCl_3	in DMSO
Amines:	δ_{NH_2} , δ_{NH}	aliphatic	<1–2	2–4
		aromatic	3–4	4–7
Ammonium:	$\delta_{\text{NH}_3^+}$, $\delta_{\text{NH}_2^+}$, δ_{NH^+}	aliphatic	7–11	7–11
		aromatic	8–12	8–12

Coupling of amine protons with vicinal H atoms is usually not seen in aliphatic amines because of their rapid intermolecular exchange. However, for =C–NH–CH moieties (enamines, aromatic amines, amides, etc.), the exchange rate is slower and splitting (or line broadening at intermediate rates) is often observed. The H–C–N–H coupling depends on the conformation in a similar way as the H–C–C–H coupling (see Chapter 5.1.2). For N–CH₃ and N–CH₂ groups: ${}^3J_{\text{HCNH}} \approx 5\text{--}6$ Hz.

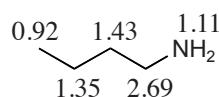

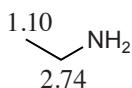

In acidic media (e.g., in trifluoroacetic acid as solvent), the exchange of the ammonium protons is slowed down to such an extent that the vicinal coupling H–N⁺–C–H generally becomes observable. In other media, signals are usually broad owing to intermediate exchange rates.

The signals of amine and especially of ammonium protons are often broadened additionally because the ${}^{14}\text{N}$ – ${}^1\text{H}$ coupling is only partly eliminated by the quadrupole relaxation of ${}^{14}\text{N}$ (spin quantum number, I = 1; natural abundance, 99.6%; ${}^1J_{\text{NH}} \approx 60$ Hz). This line broadening has no effect on the vicinal H–C–N–H coupling so that sharp multiplets can be observed for neighboring H atoms even when the NH proton exhibits a broad signal. In ammonium compounds of high symmetry, the quadrupole relaxation is slow and the coupling with ${}^{14}\text{N}$ leads to triplets of equal intensity for all three lines.

5.11.5 Amides and Lactams

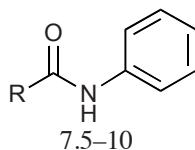

Amide Protons (δ in ppm, J in Hz)

R: alk or ar

R: alk or ar

R: alk or ar

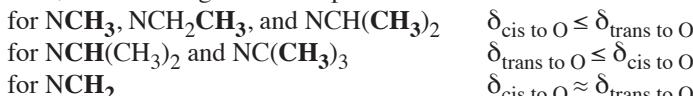

Higher values in DMSO or with H bond acceptors in the neighborhood.

The signals of the NH protons are often broad because the $^{14}\text{N}-^1\text{H}$ coupling is only partly eliminated by the quadrupole relaxation of ^{14}N (spin quantum number, $I = 1$; $^1J_{\text{NH}} \approx 60$). In primary amides, the hindered rotation around the CO–N bond is another reason for line broadening. At slow rotation, the chemical shifts of the two primary amide protons differ by about 0.4–1 ppm. Therefore, at intermediate rotation rates, line widths of up to 1 ppm may be observed.

Due to the slow intermolecular exchange of amide protons, their coupling to neighboring hydrogen atoms is usually detectable. The splitting of the C–H signal is clearly observed even in those cases where the signal of the NH proton is broad and featureless. The H–N–C–H coupling depends on the conformation in a similar way as the H–C–C–H coupling (see Chapter 5.1.2). For N–CH₃ and N–CH₂ groups: $^3J_{\text{HNCH}} \approx 7$ Hz.

Tertiary Alkylamides

The rotation around the CO–N bond is usually so slow that, for identical substituents, two separate signals are observed for *cis* and *trans* positions. With different N-substituents, two separate pairs of signals are observed for the two conformers. In general, the following relationships hold:

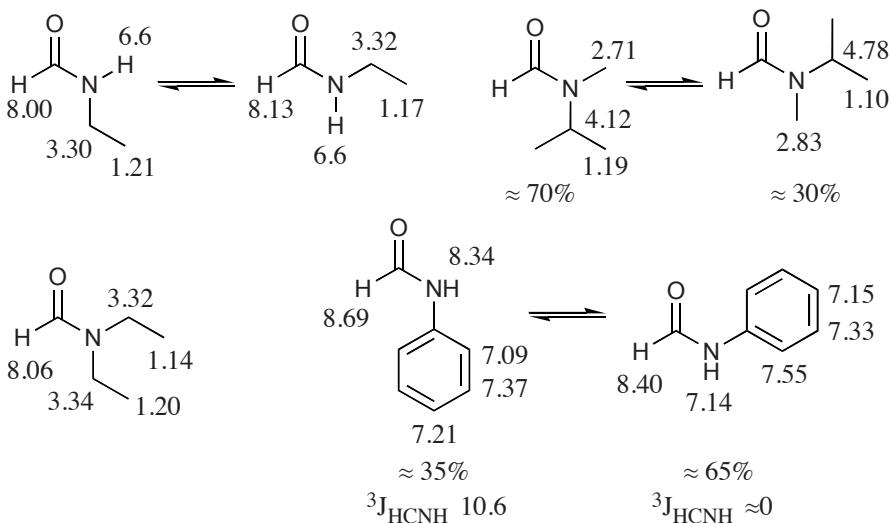

Formamides (δ in ppm, J in Hz)

In the more stable conformer of monosubstituted formamides, the substituent occupies the *cis* position relative to the carbonyl oxygen. In the more stable conformer of asymmetrically disubstituted formamides, the larger substituent occupies the *trans* position relative to the carbonyl oxygen.

5.12 Miscellaneous Compounds

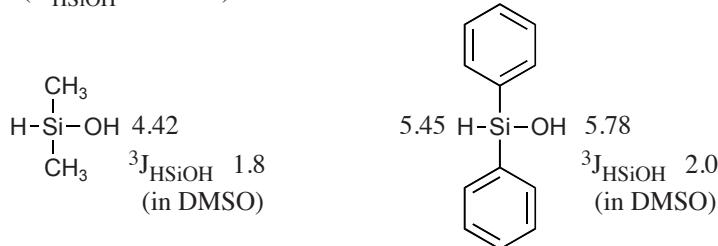

5.12.1 Compounds with Group IV Elements

Silicon Compounds (δ in ppm, J in Hz)

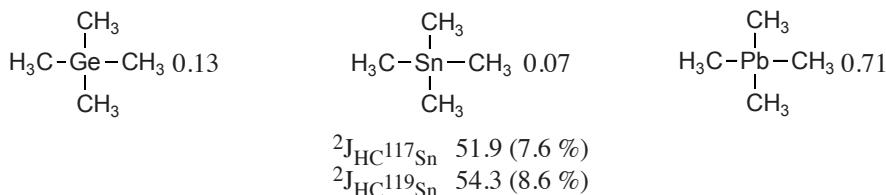

Coupling with silicon: The isotope ²⁹Si (natural abundance, 4.7 %) has a spin quantum number I of 1/2. Doublets with the corresponding intensity ("Si satellites") are usually observed. Typical coupling constants: ${}^1J_{HSi}$ -150 to -380 Hz
 ${}^2J_{HCSi}$ 5 to 10 Hz

The silanol hydrogen is exchangeable with D₂O. Slow intermolecular exchange is observed in DMSO as solvent so that the vicinal coupling in H–Si–O–H is detectable (³J_{H_{SiOH}} ≈ 2–7 Hz).

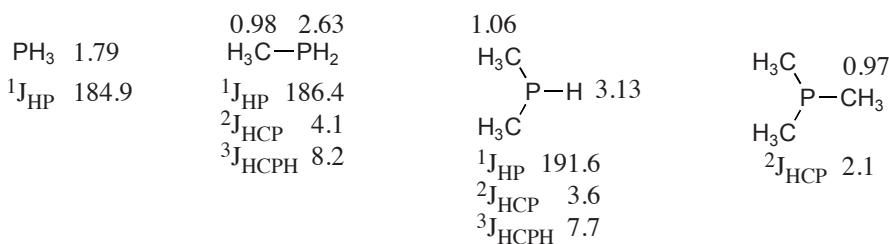

Germanium, Tin, and Lead Compounds (δ in ppm, J in Hz)

5.12.2 Phosphorus Compounds

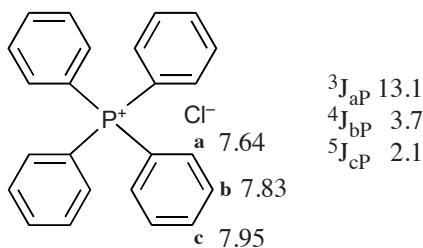

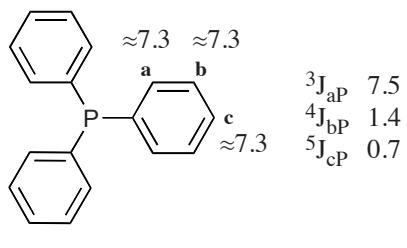

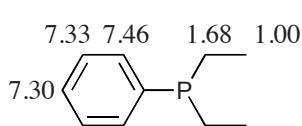

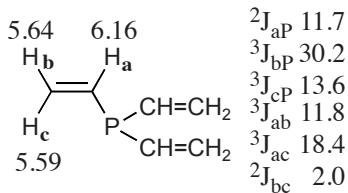

³¹P (natural abundance, 100%) has a spin quantum number I of 1/2. Couplings to protons through up to 5 bonds are usually observed.

5.14.2 ^1H NMR Spectra of Secondary Reference Compounds

Chemical shifts in ^1H NMR spectra are usually reported relative to the peak position of tetramethylsilane (TMS) added to the sample as an internal reference. If TMS is not sufficiently soluble, a capillary with TMS may be used as external reference. In this case, owing to the different volume susceptibilities, the local magnetic fields in the sample and reference differ, and the peak position of the reference must be corrected. For a D_2O solution in a cylindrical sample and neat TMS in a capillary, the correction amounts to +0.68 and -0.34 ppm for superconducting and electromagnets, respectively. These values must be subtracted from the chemical shifts relative to the external TMS signal if its position is set to 0.00 ppm. Alternatively, secondary references with $(\text{CH}_3)_3\text{SiCH}_2$ groups may be used. The following spectra of two such secondary reference compounds in D_2O were measured at 500 MHz with TMS as external reference. Chemical shifts are reported in ppm relative to TMS upon correction for the difference in the volume susceptibilities of D_2O and TMS. As a result, the peak for the external TMS appears at 0.68 ppm.

3-(Trimethylsilyl)-1-propanesulfonic acid sodium salt (sodium 4,4-dimethyl-4-silapentane-1-sulfonate; DSS)

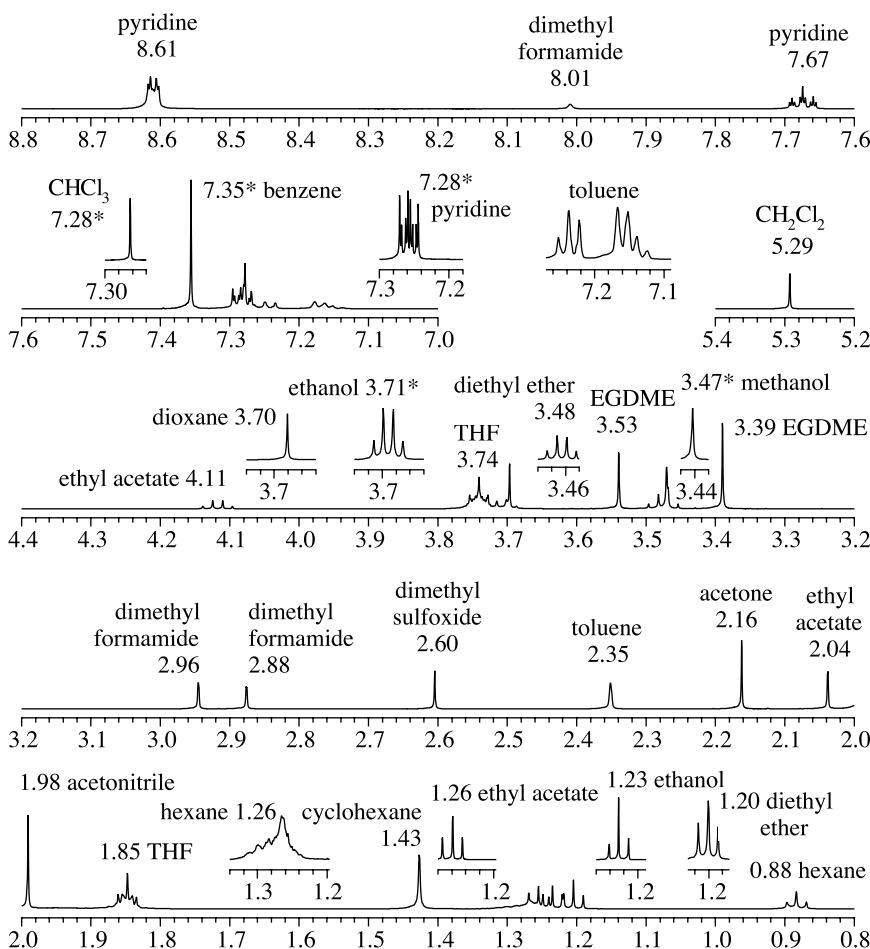

2,2,3,3-D₄-3-(Trimethylsilyl)propionic acid sodium salt

Solvents

5.14.3 ¹H NMR Spectrum of a Mixture of Common Nondeuterated Solvents

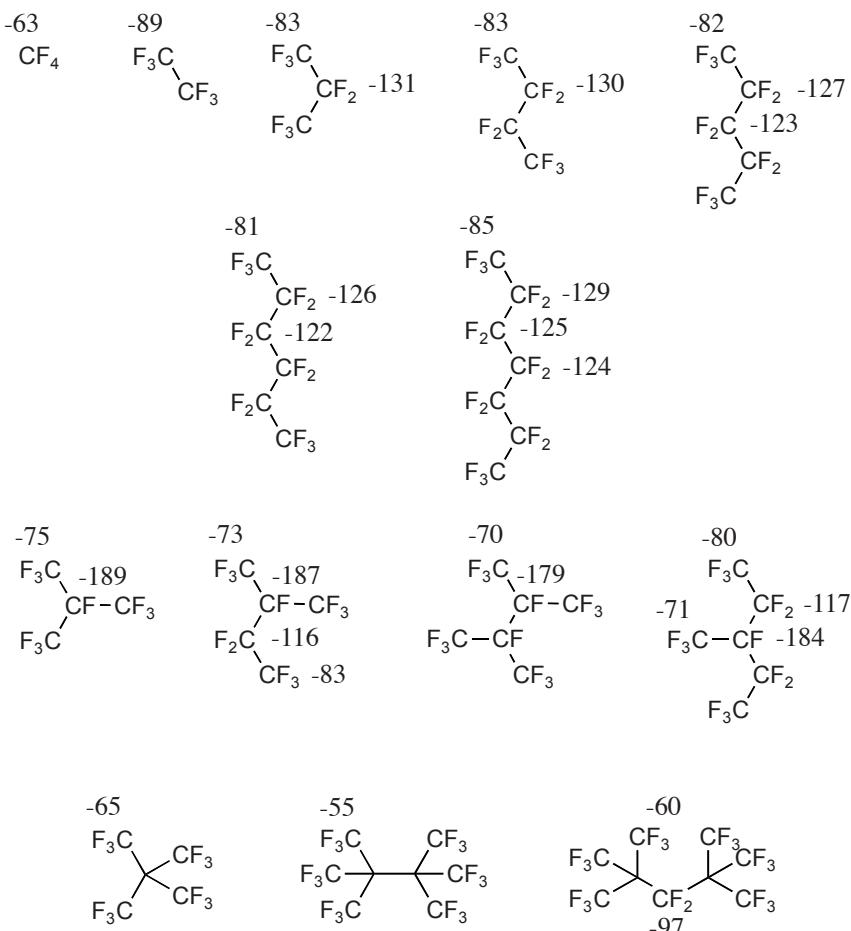

The following ¹H NMR spectrum (500 MHz, δ in ppm relative to TMS) of CDCl_3 containing 18 common solvents (0.05–0.4 vol%) is shown as a guide for the identification of possible impurities. Where the signals of several solvents overlap, insets show signals for the individual compounds from separate spectra. Peaks in these insets are labeled with the corresponding chemical shifts from their main spectrum but their values may differ by up to 0.03 ppm. Signals that are particularly prone to vary in their position are marked with *. THF: tetrahydrofuran; EGDME: ethylene glycol dimethyl ether.

Estimation of ^{19}F Chemical Shifts of Substituted Pyridines, Pyrimidines, Pyrazines, and Triazines (δ in ppm) [5]

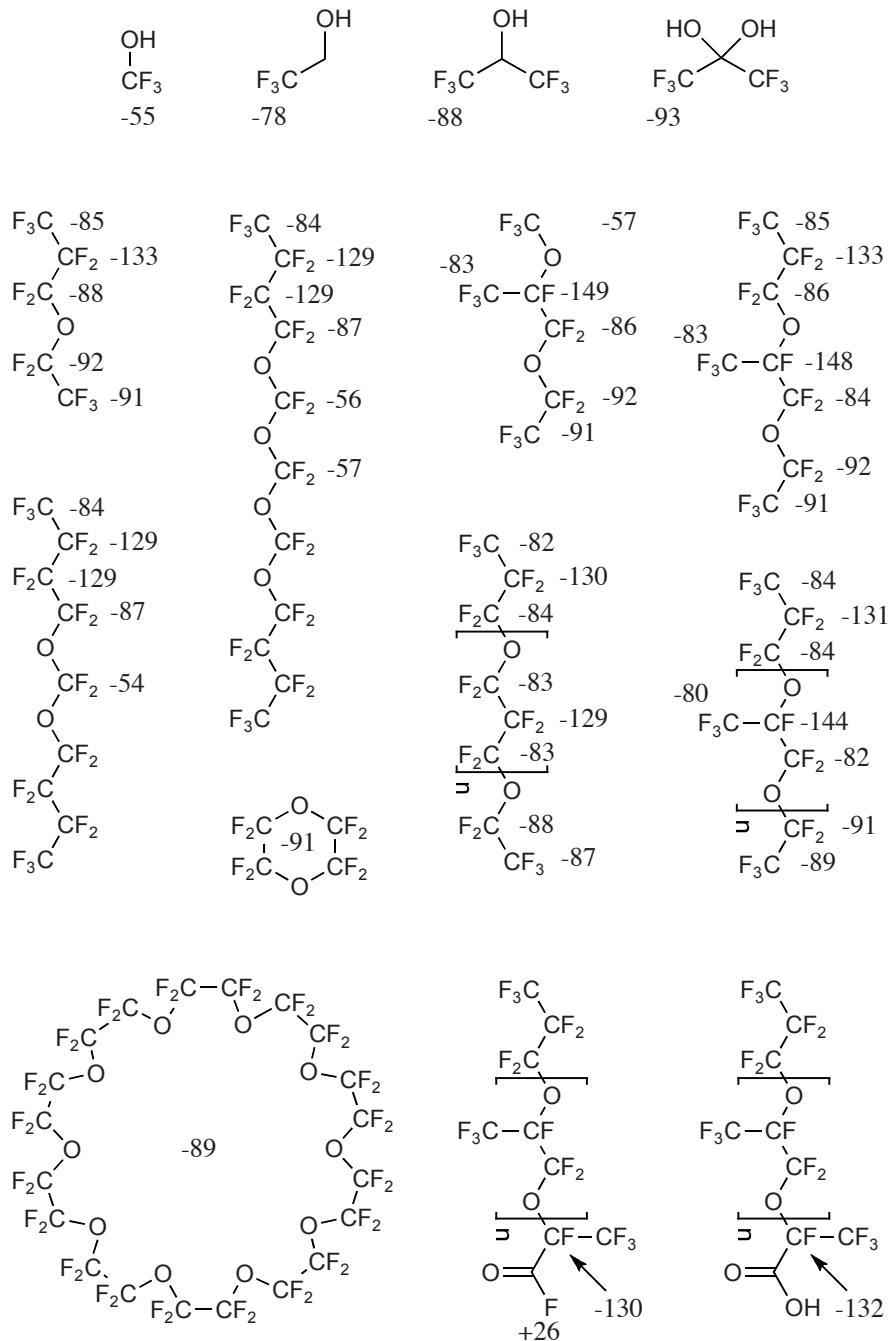

$$\delta_{\text{F}} = Y + \sum Z_i$$

To estimate the ^{19}F chemical shifts of substituted 6-ring heteroaromatics, the same increments, Z_i , can be used as for substituted fluorobenzenes (see preceding page). However, different base values, Y (as given below), apply depending on the number and position of nitrogens and the position of the fluorine substituent in question:

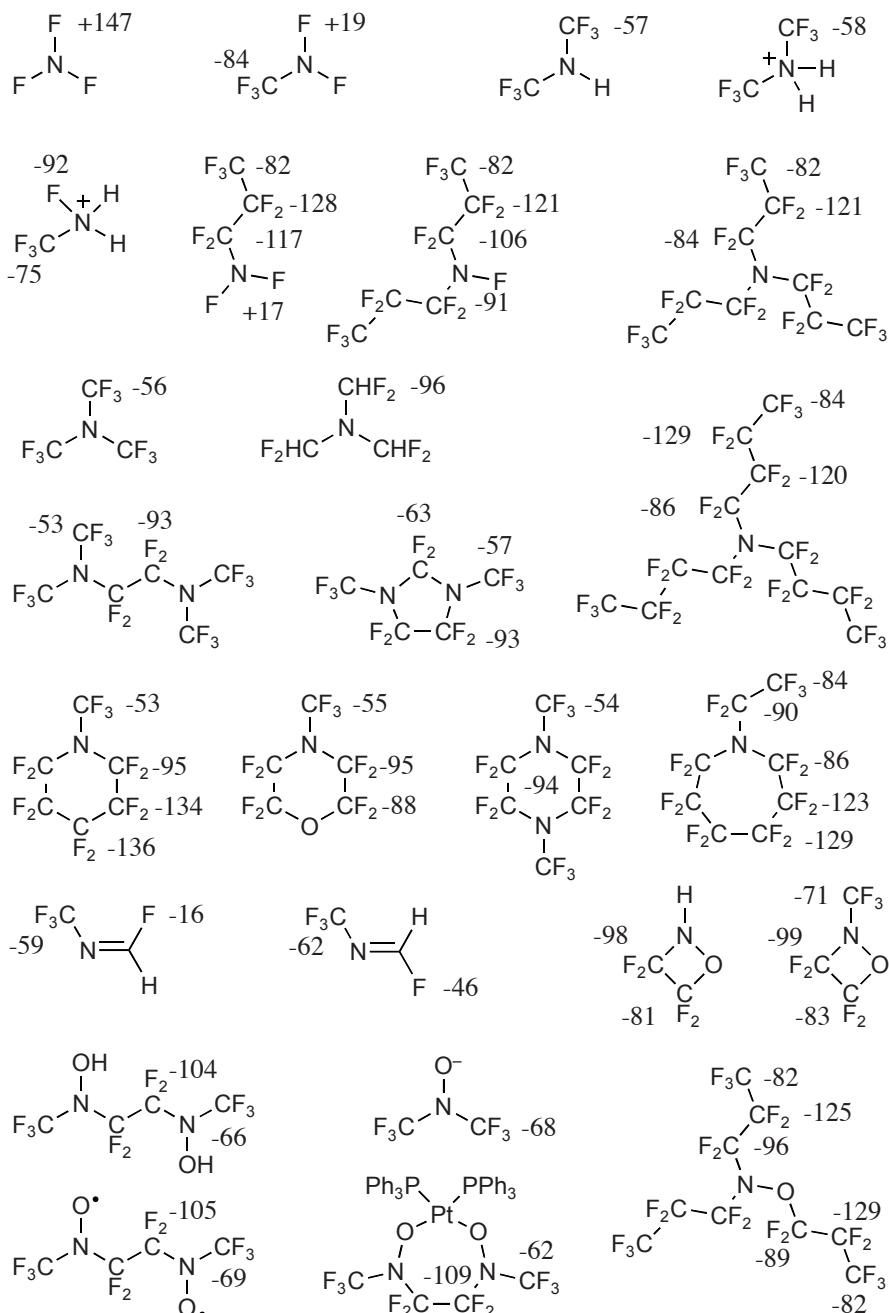

Coupling Constants in Aromatics and Heteroaromatics (J_{FF} in Hz) $^3J_{\text{FF}} -20.8$  $^4J_{\text{FF}} +6.5$  $^5J_{\text{FF}} +17.6$  $^3J_{\text{FF}} -20.3$  $^4J_{\text{FF}} -3.0$ $^5J_{\text{FF}} +3.9$ 

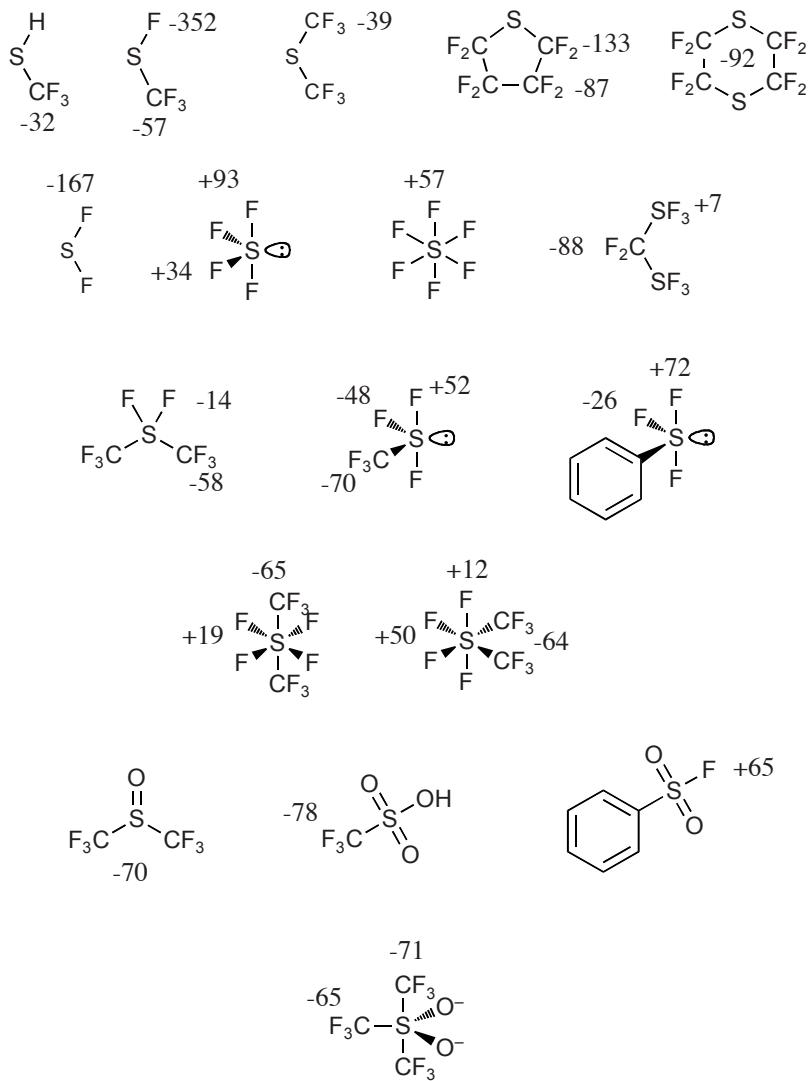

6.1.7 ^{19}F Chemical Shifts of Alcohols and Ethers (δ in ppm relative to CFCl_3)

6.1.8 ¹⁹F Chemical Shifts of Fluorinated Amine, Imine, and Hydroxyl-amine Derivatives (δ in ppm relative to CFCl_3)

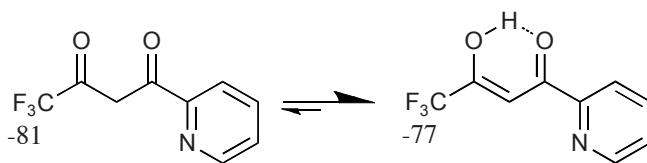

6.1.9 ^{19}F Chemical Shifts of Sulfur Compounds (δ in ppm relative to CFCl_3)

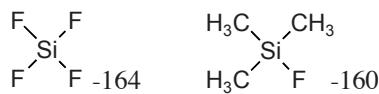

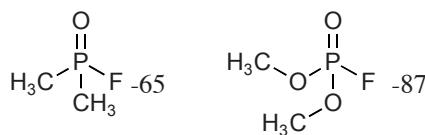

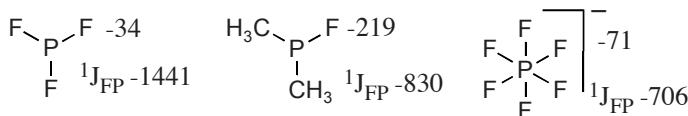

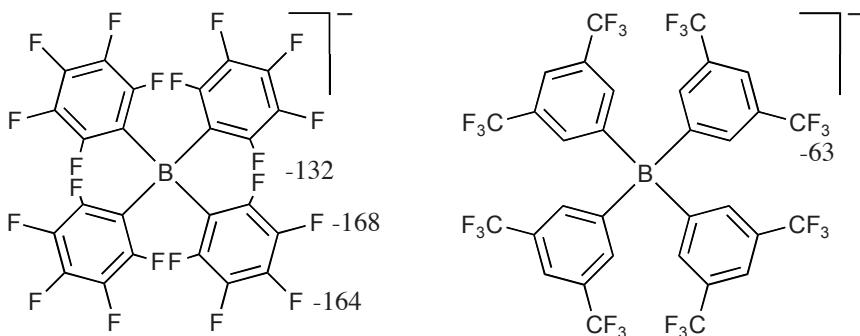

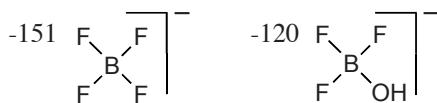

**6.1.10 ^{19}F Chemical Shifts of Carbonyl and Thiocarbonyl Compounds

7 IR Spectroscopy

7.1 Alkanes

Typical Ranges ($\tilde{\nu}$ in cm^{-1})

Assignment	Range	Comments
C–H st	3000–2840	Intensity variable, often multiplet
	Beyond normal range:	
	2850–2815	$\text{CH}_3\text{–O}$, methyl ethers
	2880–2830	$\text{CH}_2\text{–O}$, ethers
	2880–2835, 2780–2750	$\text{O–CH}_2\text{–O}$, methylenedioxy
	≈2820	O–CH–O , acetals: weak
	3050–3000	▷_O , ▷_N
	2900–2800, 2780–2750	CH=O , aldehydes: Fermi resonance
	2820–2780	$\text{CH}_3\text{–N}$, $\text{CH}_2\text{–N}$; amines
	3100–3050, 3035–2995	▷
	2930–2915, 2900–2850	 cyclohexanes: weak, comb at ≈2700
	3080–2900	CH–hal st

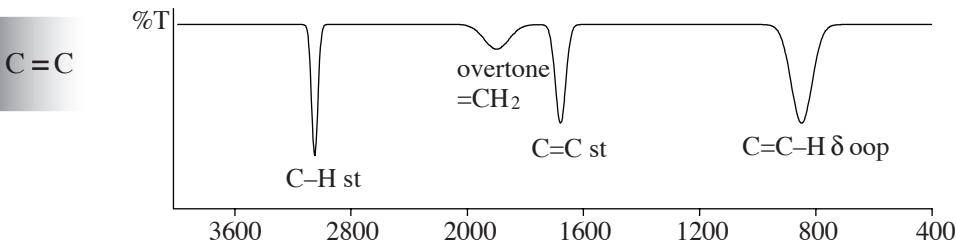

Assignment	Range	Comments
CH₃ δ as	1470–1430	Medium, coincides with CH ₂ δ <i>Beyond normal range:</i>
	1440–1400	CH ₃ –C=O, methyl ketones, acetals, CH ₃ –C=C
CH₂ δ	1475–1450	Medium, coincides with CH ₃ δ as <i>Beyond normal range:</i>
	≈1440	CH ₂ –C=C
	≈1425	CH ₂ –C≡C CH ₂ –C=O, CH ₂ –C≡N, CH ₂ –X (X: hal, NO ₂ , S, P)
CH₃ δ sy	1395–1365	Medium. Doublet in compounds with geminal methyl groups: CH(CH ₃) ₂ , of equal intensity (γ : 1175–1140, d)
	≈1385, ≈1370	≈1385, ≈1365 C(CH ₃) ₂ , 1385 weaker than 1365 (γ : 1220–1190, often d)
	≈1390, ≈1365	≈1390, ≈1365 C(CH ₃) ₃ , of equal intensity, sometimes triplet (γ : 1250–1200, d) N(CH ₃) ₂ , no doublet Solid-state spectra: sometimes doublet also in the absence of geminal methyl groups <i>Beyond normal range:</i>
	1325–1310	SO ₂ –CH ₃
	1330–1290	S–CH ₃ , sulfides
	1310–1280	P–CH ₃
	1275–1260	Si–CH ₃ , strong, sharp
CH₃ γ	1250–800	Intensity variable, of no practical significance. Strong band in compounds with geminal methyl groups: 1175–1140 CH(CH ₃) ₂ , doublet 1220–1190 C(CH ₃) ₂ , generally doublet 1250–1200 C(CH ₃) ₃ , doublet, often not resolved <i>Beyond normal range:</i>
	≈765	SiCH ₃
	≈855, ≈800	Si(CH ₃) ₂
	≈840, ≈765	Si(CH ₃) ₃

Assignment	Range	Comments
CH₂ γ	770–720	Medium, sometimes doublet C–(CH ₂) _n –C for n > 4 at \approx 720; for n < 4 at higher wavenumbers; in cyclohexanes at \approx 890, weaker
		<i>Beyond normal range:</i>
	1060–800	Cycloalkanes, numerous bands, unreliable
C–D st	2200–2080	In general, substitution of L by isotope L': $\tilde{\nu}_{X-L'} = \tilde{\nu}_{X-L} \sqrt{\frac{1/m_x + 1/m_{L'}}{1/m_x + 1/m_L}}$

7.2 Alkenes

7.2.1 Monoenes

Typical Ranges ($\tilde{\nu}$ in cm^{-1})

Assignment	Range	Comments
=CH ₂ st	3095–3075	Medium, often multiple bands
=CH st	3040–3010	Medium, often multiple bands CH st in aromatic hydrocarbons and three-membered rings fall into the same range
<i>In cyclic compounds:</i>		
	≈3075	▷
	≈3060	□
	≈3045	○
	≈3020	○
=CH δ ip	1420–1290	Of no practical significance
=CH δ oop	1005–675	A number of bands
<i>In the same range:</i> ar CH δ oop, C–O–C γ, and C–N–C γ in saturated heterocyclics, OH δ oop in carboxylic acids, NH γ, NO st, SO st, CH ₂ γ, CF st, CCl st		

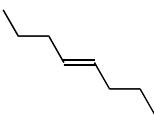

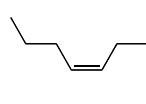

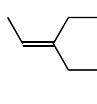

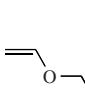

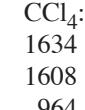

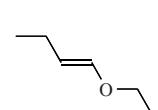

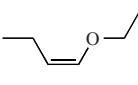

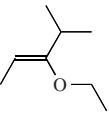

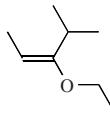

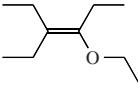

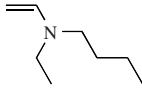

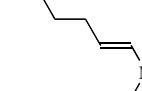

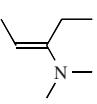

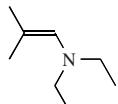

Assignment	Range	Comments		
	<i>Subranges:</i> C=C	C=C-C=O	C=C-OR	C=C-O-C=O
CH=CH ₂	1005–985 920–900 (overtone at 1850–1800)	≈980 ≈960 ≈810	≈960 ≈815	≈950 ≈870
C=CH ₂	900–880 (overtone at 1850–1780)	≈940 ≈810	≈795	
		990–960	≈975	≈960 ≈950
		725–675	≈820	
		840–800	≈820	
C=C st	1690–1635	Of variable intensity, weak for highly symmetric compounds, strong for N=C=C and O=C=C		
	<i>Subranges:</i>			
	1650–1635	CH=CH ₂		
	1660–1640	C=CH ₂		
	1690–1665	 Weak		
	1665–1635			
	1690–1660	 Weak, often absent		
	1690–1650	 Weak, often absent		
	<i>Beyond normal range:</i>			
down to ≈1590	C=C-X with X: O, N, S; of higher intensity; in vinyl ethers often doublet due to rotational isomers			

C=C

At lower frequency if conjugated with:

C=C	C=C	≈ 1650		≈ 1630
		≈ 1600		≈ 1640
	C≡N	≈ 1620		≈ 1640
	C=O	≈ 1630

7.2.2 Allenes

Typical Ranges ($\tilde{\nu}$ in cm^{-1})

Assignment	Range	Comments
$(\text{C}=\text{C})=\text{C}-\text{H}$ st	3050–2950	
$\text{C}=\text{C}=\text{C}$ st as	1950–1930	Strong, doublet in $\text{X}-\text{C}=\text{C}=\text{CH}_2$ if X other than alkyl Ring strain increases frequency: ≈ 2020
$\text{C}=\text{C}=\text{C}$ st sy	1075–1060	Weak, absent with highly symmetric substitution. In Raman, strong
$(\text{C}=\text{C})=\text{CH}_2$ δ oop	≈ 850	Strong; overtone at ≈ 1700 (weak)

7.3 Alkynes

$\text{C}\equiv\text{C}$

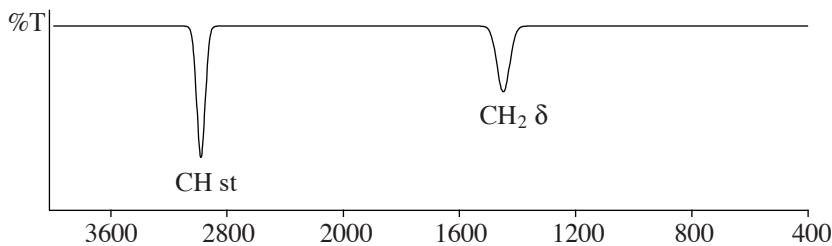

Typical Ranges ($\tilde{\nu}$ in cm^{-1})

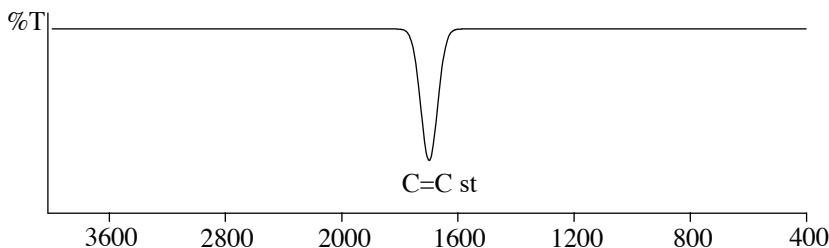

Assignment	Range	Comments
$\equiv\text{C}-\text{H}$ st	3340–3250	Strong, sharp; in the same region also OH st, NH st
$\text{C}\equiv\text{C}$ st	2260–2100	Weak, sharp. In Raman, strong
<i>Beyond normal range:</i>		
R–C≡C–H; at the lower end of the cited range		
R–C≡C–R; usually 2 bands (Fermi resonance), often missing if symmetrical, strong in Raman		
<i>Subranges:</i>		
≈2120	C–C≡C–H	
≈2220	C–C≡C–C	
≈2240	C–C≡C–CN	
≈2240	C–C≡C–COOH	
≈2240, ≈2140	C–C≡C–COOCH ₃	
<i>In the same range:</i> C≡Z st, X=Y=Z st, Si–H st		
$\equiv\text{C}-\text{H}$ δ	700–600	Strong, broad; overtone at 1370–1220 (broad, weak)

7.4 Alicyclics

Cyclic Alkanes

Cyclic Alkenes

The other vibrations are similar to those in noncyclic alkenes and cyclic alkanes.

Typical Ranges ($\tilde{\nu}$ in cm^{-1})

Assignment	Range	Comments
C–H st	3090–2860	Strong
H–C–H δ	1470–1430	Weak
C=C st	1780–1610	Varies with ring size and substitution

Twisting and wagging CH₂ as well as C–C st do not significantly differ from the corresponding vibrations in noncyclic compounds and are of limited diagnostic value.

7.5 Aromatic Hydrocarbons

Typical Ranges ($\tilde{\nu}$ in cm^{-1})

Assignment	Range	Comments
ar C–H st	3080–3030	Often numerous bands; in the same range also CH st of alkenes and small rings
ar C–C	1625–1575	 Medium, often doublet; generally weak in benzene derivatives having a center of symmetry in the ring
	1525–1450	Medium, often doublet:  Weak in: 
		In the same range: C=C st, C=N st, C=O st, N=O st, C–C in heterocyclics, NH δ
comb	2000–1650	Very weak; useful for determining substitution patterns in 6-membered aromatic rings In the same range: C=O st, B–H···B st, N ⁺ –H st, H ₂ O δ
ar C–H δ ip	1250–950	Numerous bands of variable intensity; of no practical significance. May be very strong in Raman and, thereby, indicative of substitution type

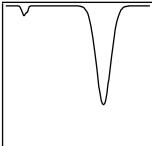

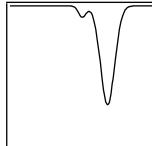

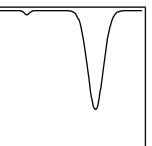

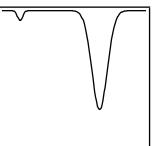

Assignment	Range	Comments
ar C–H δ oop	900–650	One or more strong bands; useful for determining substitution patterns in 6-membered aromatic rings. In Raman, generally weak <i>In the same range:</i> =C–H δ oop, C–O–C γ and C–N–C γ in saturated heterocyclics, OH δ oop in carboxylic acids, NH δ , N–O st, S–O st, CH ₂ γ , C–F δ , C–Cl st

Determination of Substitution Patterns in 6-Membered Aromatic Rings: Position and Shape of Bands Related to the Number of Adjacent H Atoms ($\tilde{\nu}$ in cm⁻¹)

Not to be used for ring systems with strongly conjugated substituents such as C=O, NO₂, C≡N.

7.6 Heteroaromatic Compounds

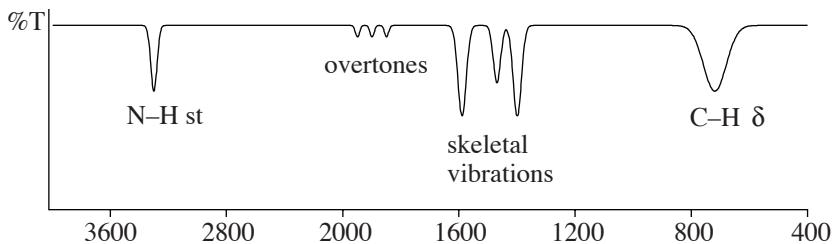

Pyridines

Furans

Pyrroles

Typical Ranges ($\tilde{\nu}$ in cm^{-1})

Assignment	Range	Comments
N–H st	3450–3200	Medium, narrow; shifted by formation of hydrogen bonds
Overtones	2100–1800	Weak, characteristic
Ring skeleton	1610–1360	Strong, sharp bands
C–H δ	1000–700	Strong, broad; difficult to identify
C–H st	3100–3000	Medium, sharp
CO–C st	1190–990	Medium or strong; of variable intensity

Pyridines:

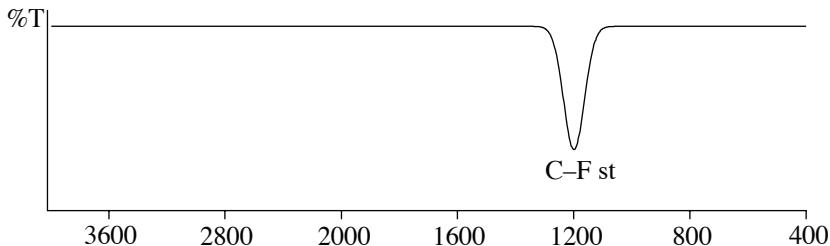

The frequencies of pyridines are very similar to those observed in benzenes. The nitrogen atom behaves like a substituted carbon atom in benzenes.

**5-Ring Heteroaromatics**

NH st free			3500–3400
NH st H-bonded			3400–2800
CH st	≈3100	≈3100	≈3100
Ring skeleton: intensity variable, generally multiplets	1610–1560 1510–1475	1590–1560 1540–1500	1535–1515 1455–1410
CH δ oop: generally strong	990–725	770–710	935–700

7.7 Halogen Compounds

7.7.1 Fluoro Compounds

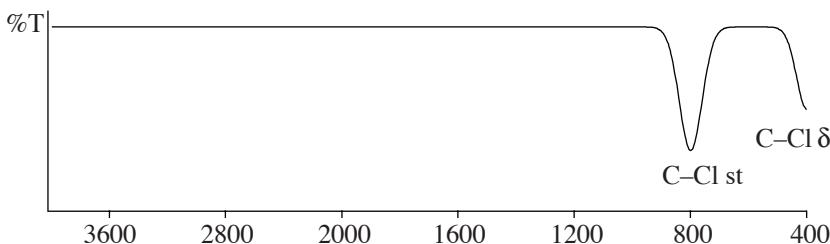

Typical Ranges ($\tilde{\nu}$ in cm^{-1})

Assignment	Range	Comments
C–F st	1400–1000	Strong, often more than one band (rotational isomers), often not resolved. In Raman, weak to medium
<i>Subranges:</i>		
	1100–1000	al CF_2 (FC–H st: 3080–2990)
	1150–1000	al CF_2
	1350–1100	al CF_3
	1350–1150	$\text{C}=\text{CF}$
	≈ 1745	$\text{C}=\text{CF}_2$ st
	1250–1100	ar CF
<i>In the same range:</i> strong bands for C–O st, NO_2 st sym, C=S st, S=O st		
CF_2	780–680	Medium or weak, assignment uncertain
CF_3	780–680	(C–F δ?)
S–F st	815–755	Strong
P–F st	1110–760	
Si–F st	980–820	
B–F st	1500–800	

Hal

7.7.2 Chloro Compounds

Typical Ranges ($\tilde{\nu}$ in cm^{-1})

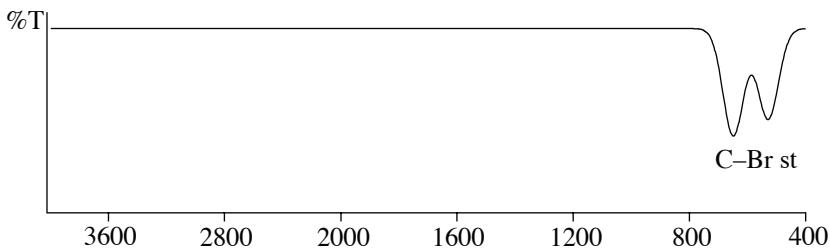

Assignment	Range	Comments
C–Cl st	830–<600	Strong, often broad (rotational isomers), absent in chloroaromatics
C–Cl δ	400–280	Of medium strength and width
Other	1100–1020	Strong, narrow or of medium width; chloroaromatics
P–Cl st	<600	
Si–Cl st	<625	
B–Cl st	1100–650	

Hal

In disubstituted halobenzenes, characteristic skeletal vibrations:

X	ortho	meta	para
Cl	1055–1035	1080–1075	1095–1090
Br	1045–1030	1075–1065	1075–1070
I			1060–1055

7.7.3 Bromo Compounds

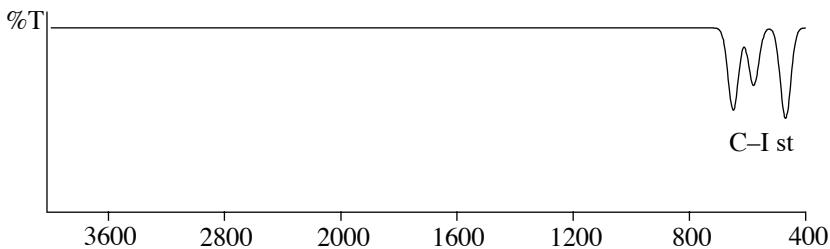

Typical Ranges ($\tilde{\nu}$ in cm^{-1})

Assignment	Range	Comments
C-Br st	700–500	Strong, of medium width; absent in bromoaromatics
C-Br δ	350–250	Of medium strength and width
Other	1080–1000	Strong, narrow or of medium width; bromoaromatics

Hal

7.7.4 Iodo Compounds

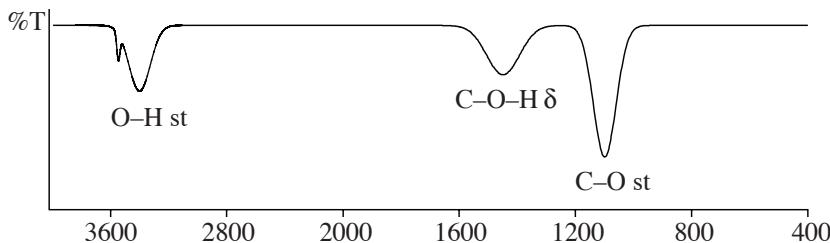

Typical Ranges ($\tilde{\nu}$ in cm^{-1})

Assignment	Range	Comments
C-I st	650–450	Strong, two or more bands
C-I δ	300–50	Of medium strength and width

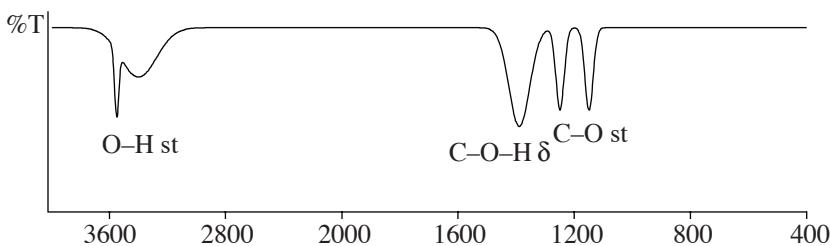

7.8 Alcohols, Ethers, and Related Compounds

7.8.1 Alcohols and Phenols

Alcohols

Phenols

O

Typical Ranges ($\tilde{\nu}$ in cm^{-1})

Assignment	Range	Comments
O-H st	3650–3200	Of variable intensity. In Raman, generally weak
	<i>Subranges:</i>	
	3650–3590	Free OH; sharp
	3550–3450	H-bonded OH; broad
	3500–3200	Polymer OH; broad, often numerous bands
	<i>Beyond normal range:</i>	
	3200–2500	Enols, chelates; often very broad
	<i>In the same range:</i>	NH st, $\equiv\text{CH}$ st (≈ 3300 , sharp), H_2O
O-H δ ip	1450–1200	Medium, of no practical significance

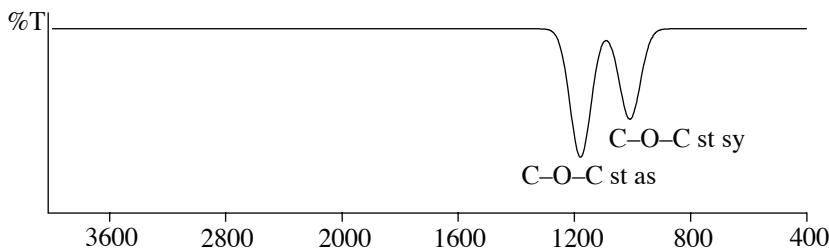

Assignment	Range	Comments
C–O st	1260–970	Strong, often doublet <i>Subranges:</i>
	1075–1000	CH ₂ –OH
	1125–1000	CH–OH
	1210–1100	C–OH
	1275–1150	ar C–OH
		<i>In the same range:</i> C–F st, C–N st, N–O st, P–O st, C=S st, S=O st, P=O st, Si–O st, Si–H δ
O–H δ oop	<700	Medium, of no practical significance

Examples ($\tilde{\nu}$ in cm^{-1})

	3250 1430 1075 1050		3335 1350		3290 1430 1020
	3215 1368 1220		3450 1370 1260 1195		3460 1315 1237 1210

O

7.8.2 Ethers, Acetals, and Ketals

In acetals and ketals, the C–O stretching vibrations are split into 3, sometimes even 4 to 5 bands.

Acetals have an additional band due to a special C–H δ vibration.

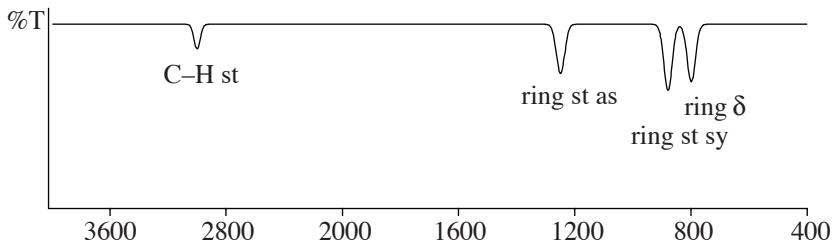

The C–H st vibration frequency is especially low for OCH₃ st (2850–2815) and OCH₂ st (2880–2835).

Typical Ranges ($\tilde{\nu}$ in cm^{-1})

Assignment	Range	Comments
C–O–C st as	1310–1000	Strong, sometimes split
<i>Subranges for noncyclic ethers:</i>		
1150–1085	$\text{CH}_2\text{—O—CH}_2$	
1170–1115	CH—O—CH , often split	
1225–1180	C=C—O—al C	
1275–1200	ar C–O–al C

7.8.3 Epoxides*Typical Ranges ($\tilde{\nu}$ in cm^{-1})*

Assignment	Range	Comments
C–H st	3050–2990	Frequency higher than normally found in alkanes
ring st as	1280–1230	Variable intensity
ring st sy	950–815	Variable intensity
ring δ	880–750	Variable intensity

Examples ($\tilde{\nu}$ in cm^{-1})

	1280 870		1230 sy 885 as 845 δ		1260 sy 890 as 780 δ
--	-------------	--	----------------------------	--	----------------------------

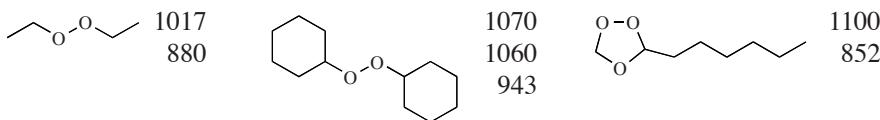

7.8.4 Peroxides and Hydroperoxides

Typical Ranges ($\tilde{\nu}$ in cm^{-1})

Assignment	Range	Comments
O–O–H st	3450–3200	Of variable intensity
	<i>Subranges:</i>	
	≈3450	Free OOH; H-bonded: ≈30 cm^{-1} higher than in corresponding alcohols
	<i>In the same range:</i> OH st, NH st, ≡CH st, H_2O	
C–O–O st	1200–1000	Strong, ≈20 cm^{-1} lower than in corresponding alcohols
	<i>In the same range:</i> strong bands for C–O st, C–F st, C–N st, N–O st, P–O st, C=S st, S=O st, P=O st, Si–O st, Si–H δ	O
O–O st	1000–800	Medium or weak, often doublet, assignment uncertain
Also:	1760–1745	C=O st in peracids
	1820–1770	C=O st in diacylperoxides (two bands)

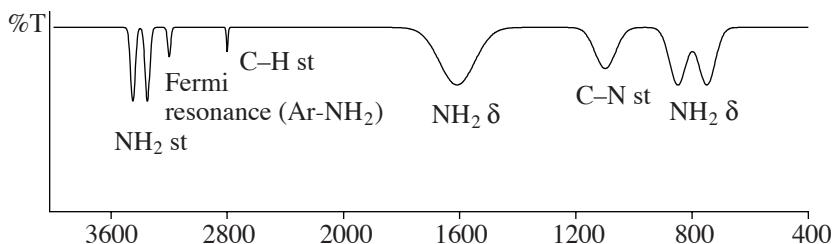

Examples ($\tilde{\nu}$ in cm^{-1})

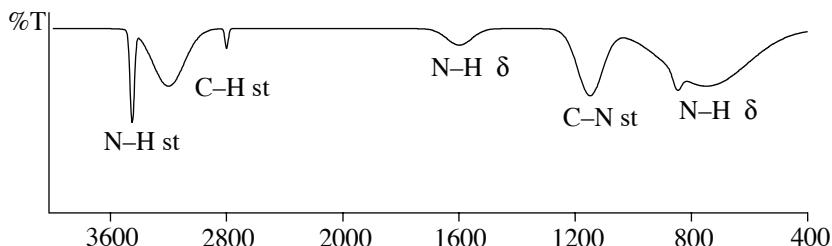

7.9 Nitrogen Compounds

7.9.1 Amines and Related Compounds

Primary Amines

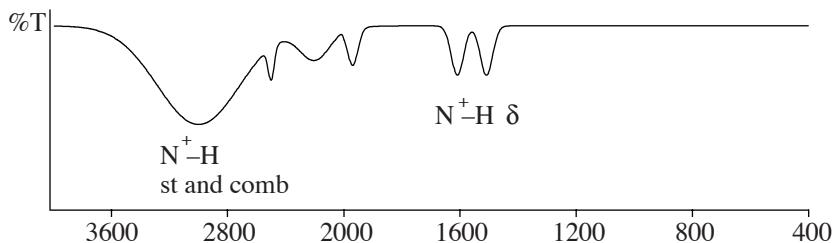

Secondary Amines

N

Ammonium

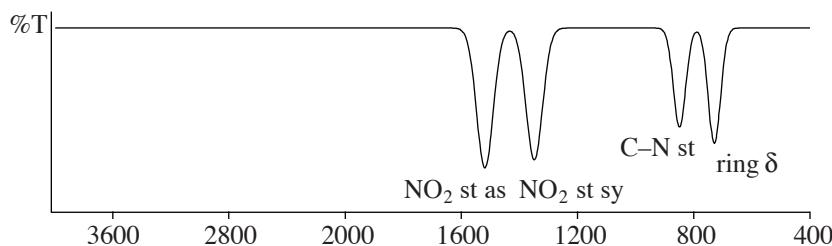

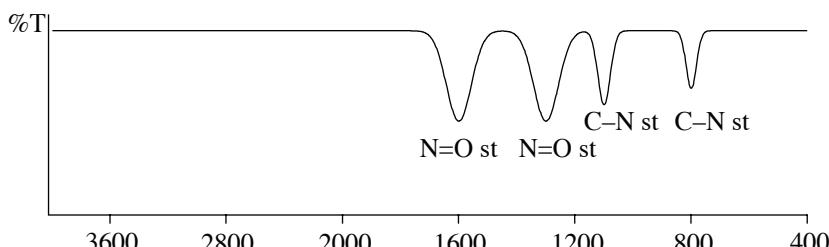

Typical Ranges ($\tilde{\nu}$ in cm^{-1})

Assignment	Range	Comments
NH₂ st	3500–3300	Of variable intensity, generally 2 sharp bands, $\Delta\tilde{\nu} = 65\text{--}75$ At lower wavenumbers (<3200) and broader if H-bonded. Free and H-bonded forms often simultaneously observed In primary aromatic amines, additional combina- tion band at ≈ 3200 <i>In the same range:</i> OH st, $\equiv\text{CH}$ st
NH st	3450–3300	Of variable intensity, only one band At lower wavenumbers (<3200) and broader if H-bonded. Free and H-bonded forms often simultaneously observed <i>In the same range:</i> OH st, $\equiv\text{CH}$ st, H ₂ O
NH₃⁺ st	3000–2000 3000–2700	Medium, broad, highly structured Major maximum, comb: ≈ 2000
NH₂⁺ st	3000–2000 3000–2700	Medium, broad, highly structured Major maximum
NH⁺ st	3000–2000 2700–2250	Medium, broad, highly structured Major maximum <i>In the same range:</i> OH st, NH st, CH st, SH st, PH st, SiH st, BH st, X=Y=Z st, X≡Y st
NH₂ δ	1650–1590	Medium or weak
NH δ	1650–1550	Weak
NH₃⁺ δ	1600–1460	Medium, often more than one band; weak in aliphatic amines
NH₂⁺ δ	1600–1460	Medium, often more than one band; weak in aliphatic amines
NH⁺ δ	1600–1460	Medium, often more than one band; weak in aliphatic amines
C–N st	1400–1000	Medium, of no practical significance
NH₂ δ	850–700	Medium or weak; 2 bands in primary amines
NH δ	850–700	Medium or weak

7.11 Carbonyl Compounds

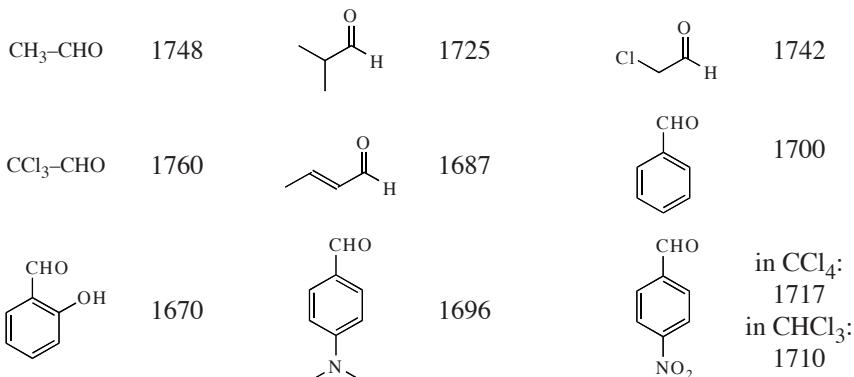

7.11.1 Aldehydes

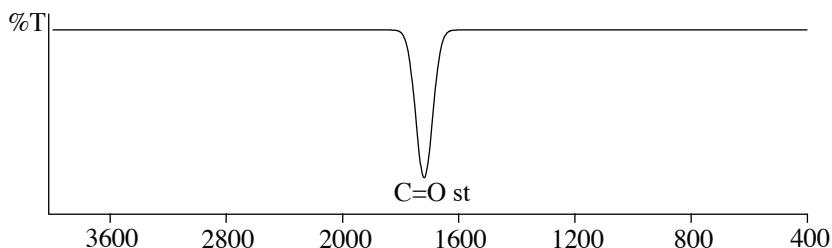

Typical Ranges ($\tilde{\nu}$ in cm^{-1})

Assignment	Range	Comments
C–H comb	2900–2800 2780–2680	Weak, Fermi resonance with C–H δ at ≈ 1390 (for extreme position of C–H δ only one band)
	<i>Subranges:</i> 2830–2810, 2720–2690	Aliphatic
	2830–2810, 2750–2720	Aromatic, with <i>o</i> -substitution often higher
	<i>In the same range:</i> cyclohexanes at ≈ 2700 , weak	
C=O st	1765–1645	Strong; in Raman, weak to medium
	<i>Subranges:</i> 1740–1720 1765–1730 1710–1685 1695–1660 1670–1645	Aliphatic α -Halogenated aliphatic Aromatic α,β -Unsaturated aromatic With intramolecular H bonds
C=X	C–H δ	1390
		Weak, of no practical significance

Examples ($\tilde{\nu}$ in cm^{-1})

7.11.2 Ketones

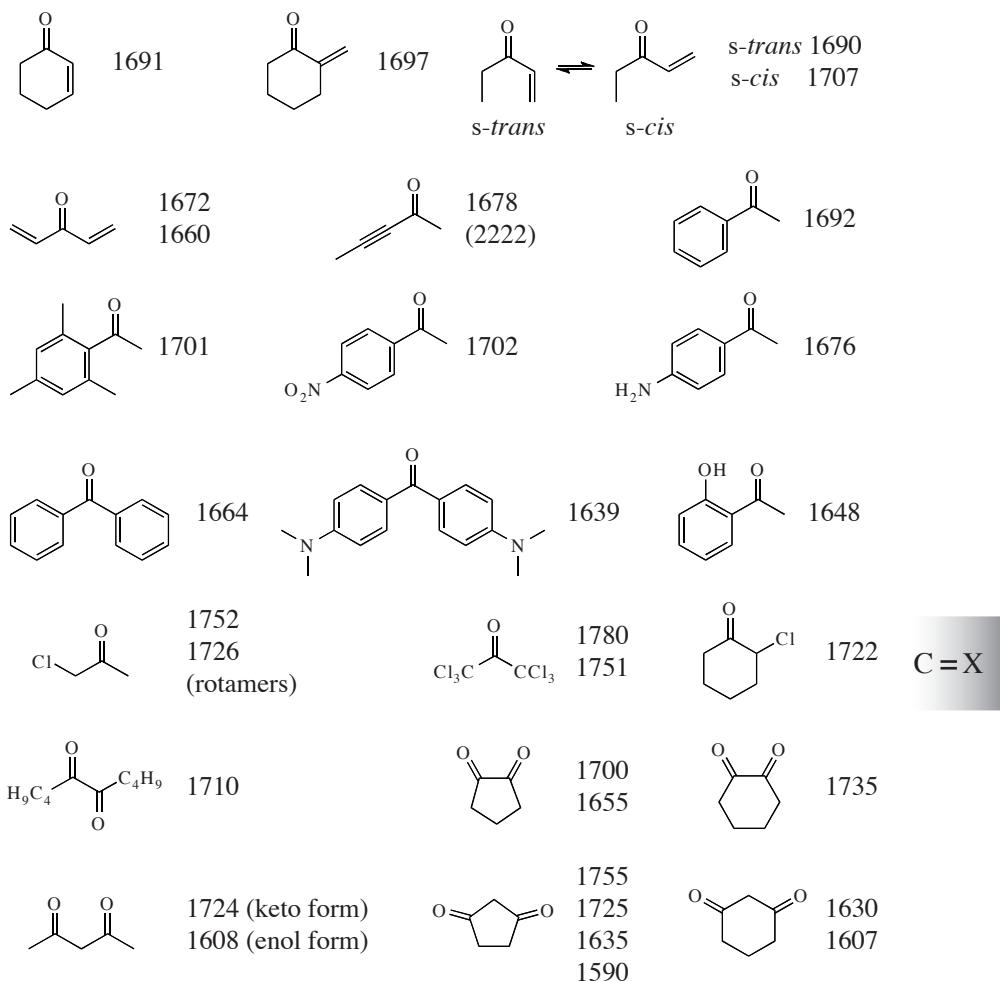

Typical Ranges ($\tilde{\nu}$ in cm^{-1})

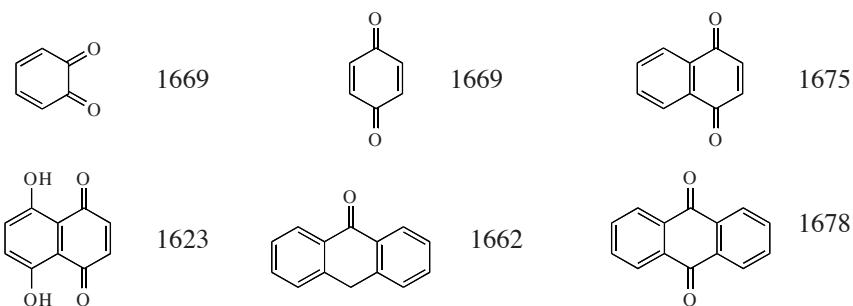

Assignment	Range	Comments				
C=O st	1775–1650	Strong; in Raman, weak to medium				
	<i>Subranges:</i> ≈ 1715	Aliphatic, branching at α position causes shift to lower wavenumbers:				
			≈ 1695		≈ 1685	C = X
	≈ 1775 –1705	Cyclic, $\tilde{\nu}$ decreases with increasing ring size [contd.]				

Assignment	Range	Comments
		≈1775
		≈1750
		≈1715
		≈1705
Conjugated:	≈1675	α,β-Unsaturated, often 2 bands (rotational isomers)
	1650–1600	C=C st
	≈1695	
		al
	≈1665	α,β,γ,δ-Diunsaturated; α,β;α',β'-diunsaturated
	≈1670	
		C=C
	≈1690	Aryl ketones
	≈1675	
		ar
	≈1665	Diaryl ketones, with N or O in <i>p</i> -position: down to ≈1600
α-Halogenated ketones:	Shifted toward higher wavenumbers depending on dihedral angle φ between C=O and C-hal; largest effect for φ = 0°, no effect for φ = 90°	
	Maximal shifts:	
	α-chloro	≈25
	α,α-dichloro	≈45
	α,α'-dichloro	≈45
		α-bromo ≈20
		α-iodo ≈0
		α,α-difluoro ≈60
		perfluoro ≈90
C=X	α-Diketones:	≈1720 Aliphatic
		≈1775, ≈1760 Aliphatic 5-ring
		≈1760, ≈1730 Aliphatic 6-ring
		≈1675 Aliphatic enolized, C=C st: ≈1650
		≈1680 Aromatic
		≈1675 <i>o</i> -Quinones, with <i>peri</i> -OH: ≈1675, ≈1630
	β-Diketones:	≈1720 Keto form, sometimes doublet
		≈1650 Enol form

Assignment	Range	Comments
	≈1615	Enol with intramolecular H bonds, C=C st: ≈1600, strong
γ-Diketones:	≈1675	As monoketones
	p-Quinones; with peri-OH: ≈1675, ≈1630 C=C st: ≈1600	
C=C=O st as	2155–2130	Very strong

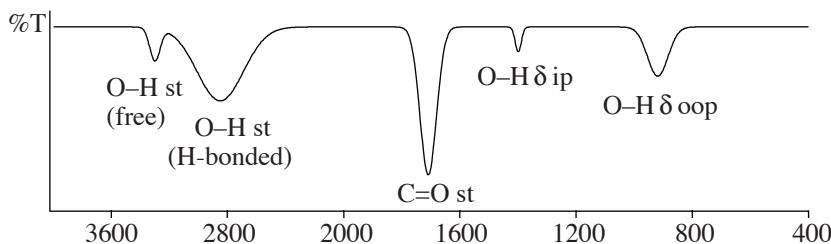

Examples ($\tilde{\nu}$ in cm^{-1})

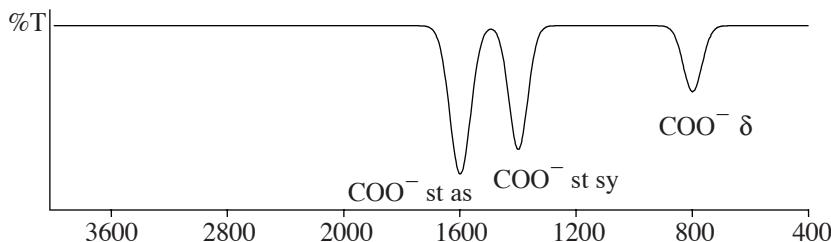

7.11.3 Carboxylic Acids

Carboxylic Acids

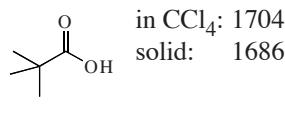

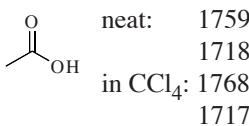

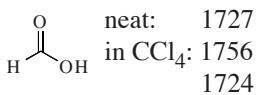

Carboxylate Anions

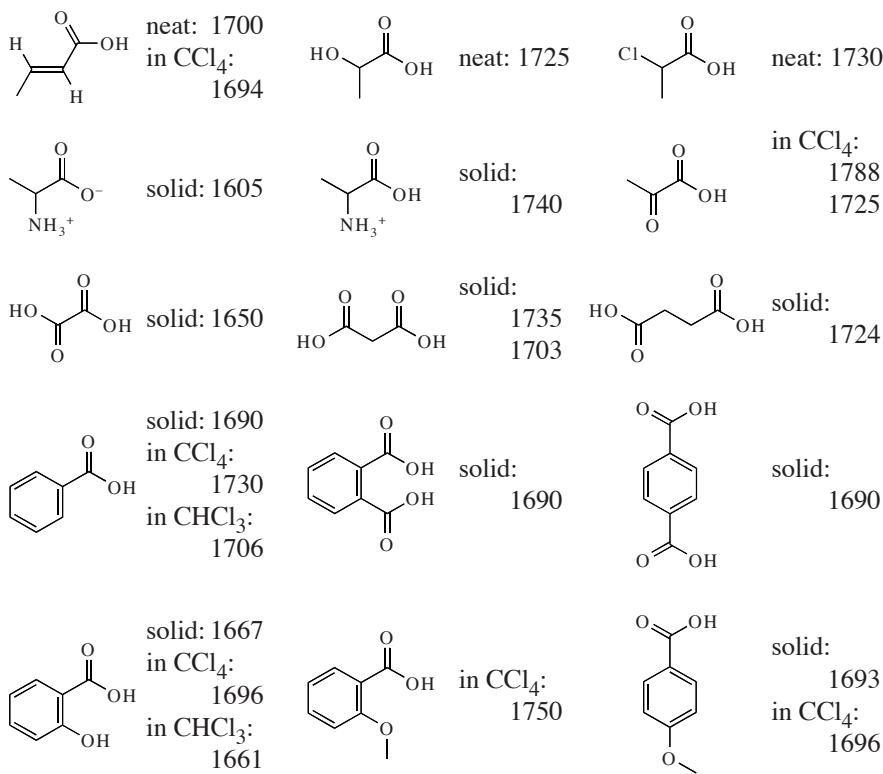

C=X

Typical Ranges ($\tilde{\nu}$ in cm^{-1})

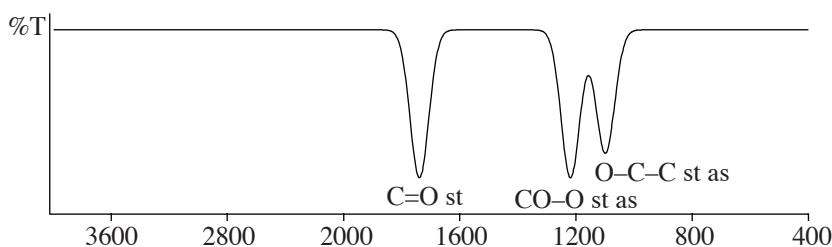

Assignment	Range	Comments
COO-H st	3550–2500	Intensity variable
	<i>Subranges:</i>	
	3550–3500	Free, sharp, only in highly diluted solutions
	3300–2500	H-bonded, broad, often more than one band
	<i>In the same range:</i> OH st, NH st, CH st, SiH st, SH st, PH st	
C=O st	1800–1650	Strong; in Raman, weak to medium
	1800–1740	Free (also in dicarboxylic acids)
	1740–1650	H-bonded (dimer, also in dicarboxylic acids)
	<i>Subranges for H-bonded C=O:</i>	
	1725–1700	al-COOH
	1715–1690	C=C-COOH
	1700–1680	ar-COOH
	1740–1720	hal-C-COOH
	1670–1650	Intramolecular H bond
OC-OH st, C-OH δ	1440–1210	Of no practical significance
OC-OH δ oop	960–880	Medium, generally broad (only in dimers); in the same range: =CH δ, ar CH δ, NH δ
(COO)⁻ st as	1610–1550	Very strong; in α-halogen carboxylates near the higher value, with more than one α-hal beyond the normal range; in polypeptides at ≈ 1575
(COO)⁻ st sy	1450–1400	Strong, of no practical significance, in polypeptides at ≈ 1470
(COO)⁻ δ	≈775	Formates, weak
	≈925	Acetates
	≈680	Benzoates
	≈600	CF_3COO^-

	≈1595	Na ⁺ salts

7.14 Solvents, Suspension Media, and Interferences

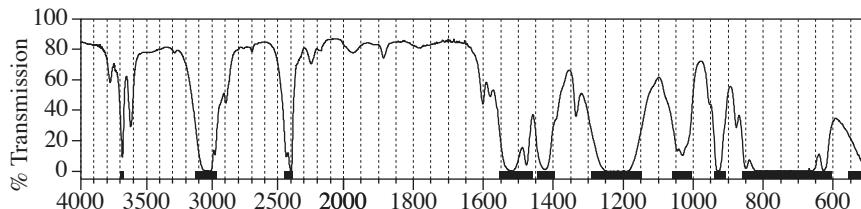

7.14.1 Infrared Spectra of Common Solvents

The low transmission in regions where the solvent absorbs may lead to artifacts. For the interpretation of spectra, these regions should be disregarded. In the following, they are indicated by bars.

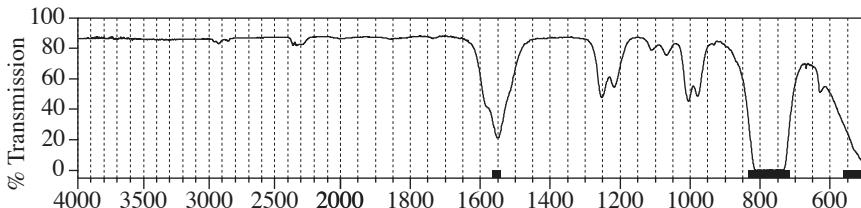

Chloroform: 0.2 mm cell

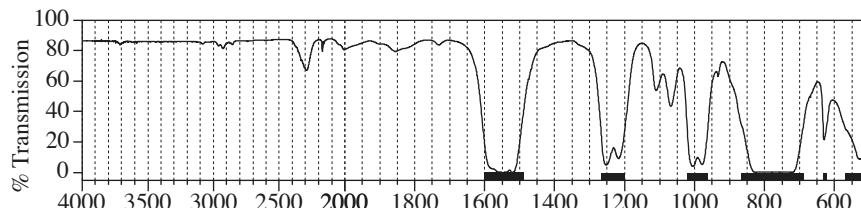

Chloroform: 1 mm cell

Carbon tetrachloride: 0.2 mm cell

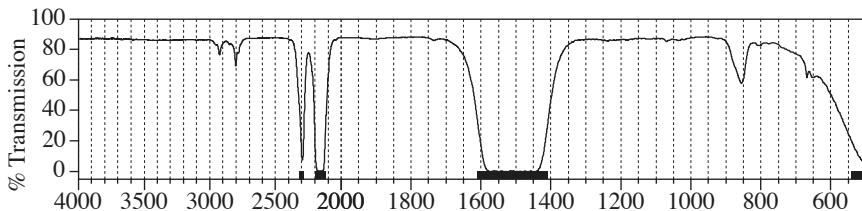

Carbon tetrachloride: 1 mm cell

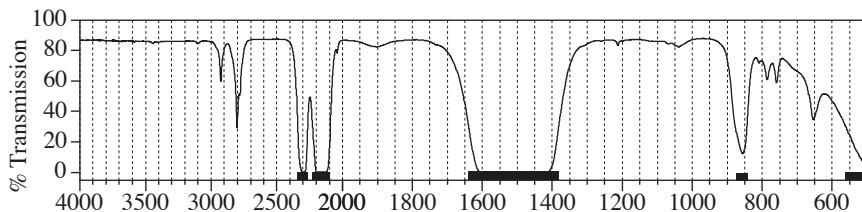

Solvents

Carbon disulfide: 0.2 mm cell

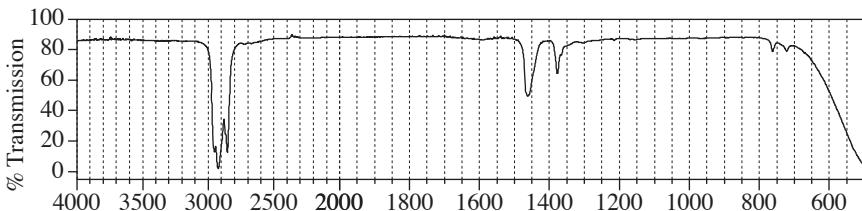

Carbon disulfide: 1 mm cell

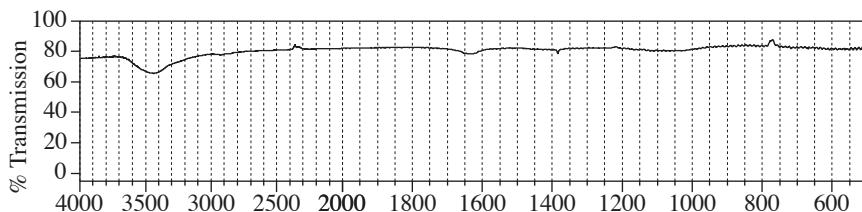

7.14.2 Infrared Spectra of Suspension Media

As it is difficult to prepare pellets and thin mineral oil films of reproducible thickness, the bands of these suspension matrixes are always found superimposed on the sample spectra.

Mineral oil (nujol): 10 μm thickness

Potassium bromide: pellet

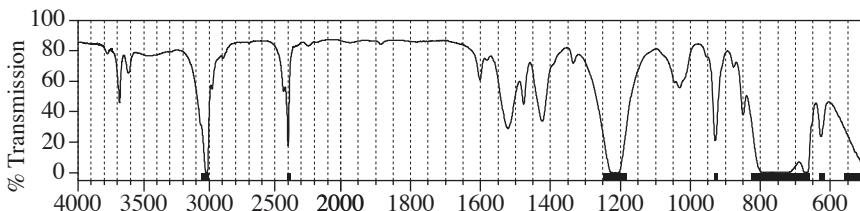

7.14.3 Interferences in Infrared Spectra

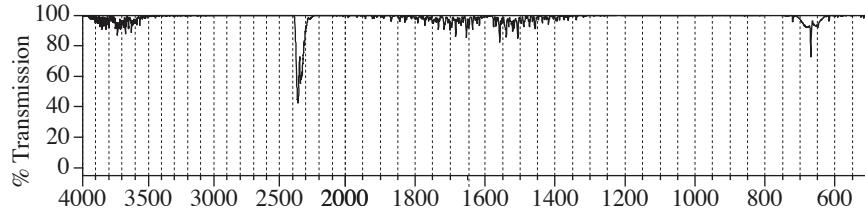

Traces of water in carbon tetrachloride or chloroform may give rise to two bands in the vicinity of 3700 and 3600 cm^{-1} as well as one around 1600 cm^{-1} . At higher concentrations, a broad band at 3450 cm^{-1} is found. Water in the vapor phase exhibits many sharp bands between 2000 and 1280 cm^{-1} . If present in high concentration, they may temporarily block the detector and appear as shoulders when occurring at a steep side of a strong signal.

Dissolved carbon dioxide shows an absorption band at 2325 cm^{-1} . In solutions that contain amines and traces of water, CO_2 can form carbonates, which lead to the appearance of unexpected bands of protonated N-containing groups. In improperly balanced double beam instruments, gaseous CO_2 can give rise to two signals at approximately 2360 and 2335 cm^{-1} as well as a signal at 667 cm^{-1} .

Chloroform, saturated with water: 0.2 mm cell

Water vapor with carbon dioxide

Commercially available polymers often contain phthalates as plasticizers, which can be found in apparently pure samples and give rise to a band at 1725 cm^{-1} . The presence of such phthalates can be confirmed by MS (m/z 149). In the course of chemical reactions, phthalates may be transformed into phthalic anhydride, which shows a band at 1755 cm^{-1} .

Other frequently encountered contaminants are silicones, which generally exhibit a band at 1625 cm^{-1} , together with a broad signal in the region from 1100 to 1000 cm^{-1} .

8 Mass Spectrometry

8.1 Alkanes [1]

Unbranched Alkanes [2,3]

Fragmentation: Larger alkyl fragments (with $C_{n>4}$) are chiefly formed by direct cleavage. They dehydrogenate and undergo substantial H and skeleton rearrangements. Smaller alkyl fragments (C_2 to C_4) are mainly formed by secondary decomposition of higher alkyl fragments. Eliminations of groups from within the chain (and recombination of its ends) also occur.

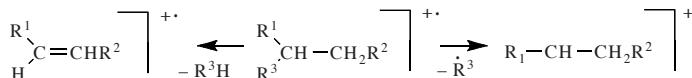

Ion series: Consecutive peaks corresponding to C_nH_{2n+1} (m/z 29, 43, 57, 71, ...), accompanied by C_nH_{2n-1} (m/z 27, 41, 55, 69, ...) and C_nH_{2n} (m/z 28, 42, 56, 70, ...) of lower intensity.

Intensities: Maximum intensity at m/z 43 or 57; with increasing masses, intensity of local maxima smoothly decreasing to a minimum at $[M-15]^+$.

Molecular ion: Medium intensity.

Branched Alkanes [2,3]

Fragmentation: In most cases, apparently simple bond cleavages, preferably at branched C atoms. The positive charge remains mainly on the branched C atom. Mechanistically, many H and skeleton rearrangements take place. This is reflected by the fact that no specific localization of heavy isotopes is possible.

Ion series: Consecutive peaks corresponding to C_nH_{2n+1} (m/z 29, 43, 57, 71, ...), accompanied by C_nH_{2n-1} (m/z 27, 41, 55, 69, ...) and C_nH_{2n} (m/z 28, 42, 56, 70, ...) of lower intensity.

Intensities: Local intensity maxima at those masses that result from cleavage at branched C atoms if the charge is localized there. Both C_nH_{2n+1} and (often more characteristically) C_nH_{2n} show this tendency.

Molecular ion: Intensity decreasing with increasing degree of branching. No M^{+*} is observed in highly branched systems.

8.2 Alkenes [1–4]

Unbranched Alkenes

Fragmentation: Dominant loss of alkyl residues and neutral alkenes. The position of highly substituted double bonds can be localized because in this case alkene eliminations are specific McLafferty-type reactions. Otherwise, double bonds can be localized in derivatives, such as epoxides and glycols, or by means of low energy ionization techniques. Branching effects are less characteristic than in isoalkanes. Alicyclic compounds exhibit very similar spectra.

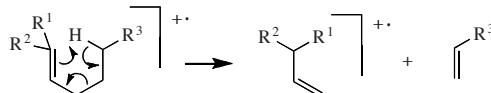

Ion series: Consecutive peaks corresponding to $\text{C}_n\text{H}_{2n-1}$ (m/z 41, 55, 69, 83, ...), accompanied by alkyl and alkene ions, $\text{C}_n\text{H}_{2n+1}$ (m/z 43, 57, 71, 85, ...) and C_nH_{2n} (m/z 42, 56, 70, 84, ...), mostly of lower intensity.

Intensities: Dominant maxima in the lower mass range, peaking around C_4 . Local even-mass maxima due to alkene eliminations if the double bond is highly substituted.

Molecular ion: Significant, but not necessarily strong.

Branched Alkenes

Fragmentation: Highly substituted double bonds are less easily displaced than the unsubstituted ones and give rise to specific alkene eliminations of the McLafferty type, resulting in significant local maxima corresponding to C_nH_{2n} (see scheme). The latter may allow to localize the double bond. With unsubstituted double bonds, no reliable localization is possible and only moderately useful branching effects can be observed. The branching position is more easily determined after reduction to an alkane (in situ in GC/MS with H_2 as carrier gas and heated Pt wool as catalyst).

Ion series: Maxima of the alkene type ($\text{C}_n\text{H}_{2n-1}$; m/z 41, 55, 69, 83, ...), accompanied by weaker alkyl fragments, $\text{C}_n\text{H}_{2n+1}$ (m/z 43, 57, 71, 85, ...), in the low mass range and more significant alkene ions, C_nH_{2n} (m/z 42, 56, 70, 84, ...).

Intensities: Intensive peaks in the lower mass range. Diagnostically important local maxima of even mass, frequently also in the higher mass range.

Molecular ion: Usually significant.

Polyenes and Polyynes

Fragmentation: The spectra of aliphatic compounds with several triple and/or double bonds are similar to those of aromatic hydrocarbons. A characteristic difference in the case of polyenes and polyynes is the presence of a signal at m/z 27, which is absent from spectra of purely aromatic compounds.

Ion series: Very similar to those of aromatic hydrocarbons, but fragments with higher hydrogen contents than in aromatics (m/z 54, 55; 66, 67; 79, 80) are usually found in polyenes and polyynes.

Intensities: Very similar distribution of peak intensities as for aromatic hydrocarbons.

Molecular ion: Usually strong, as in aromatic hydrocarbons.

8.3 Alkynes [1]

Aliphatic Alkynes

Fragmentation: Tendency to lose a non-acetylenic H⁺ from M⁺. Extensive rearrangements (including consecutive McLafferty rearrangements to the triple bond) result in uncharacteristic degradation:

In nonbranched alkynes with C_n>8, the rearrangement products at m/z 82 and 96 are dominant. Consecutive loss of methyl radical occurs. In general, no reliable localization of the triple bond is possible except in derivatives (as in ethylene glycol adducts [1], see scheme).

Ion series: Prominent peaks for C_nH_{2n-3} (m/z 25, 39, 53, 67, 81, ...), accompanied by C_nH_{2n-1} (m/z 41, 55, 69, 83, ...) and alkyl ions C_nH_{2n+1} (m/z 43, 57, 71, 85, ...). Occasionally, even-mass maxima for C_nH_{2n-2} (m/z 26, 40, 54, 68, 82, ...).

Intensities: Intensive peaks mainly in the lower mass range.

Molecular ion: Weak or missing in spectra of smaller molecules, significant in those of larger ones. Generally, [M-1]⁺ is present. In terminal acetylenes, it is normally more abundant than M⁺.

- [1] C. Lifshitz, A. Mandelbaum, Mass spectrometry of acetylenes. In: *The Chemistry of the Carbon-Carbon Triple Bond, Part 1*; S. Patai, Ed.; Wiley: Chichester, 1978; p 157.

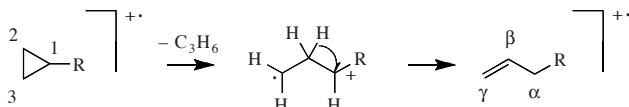

8.4 Alicyclics [1]

Cyclopropanes [2,3]

Fragmentation: Generally, spectra of cyclopropanes and alkenes are very similar because at 70 eV ionization, the ring readily isomerizes to the corresponding alkene radical cations.

Preferred primary fragmentation by bond cleavage at branched C atoms. Loss of alkyl residues and of neutral alkenes dominates. The ring of monosubstituted cyclopropanes is opened exclusively at the 1,2- and not at the 2,3-bond. The primarily formed double bond is predominantly (for R: OCH₃) or exclusively (for R: H, alk, COOCH₃) found in the β,γ-position (even for COOCH₃, where the α,β-unsaturation is thermodynamically more stable).

Molecular ions of cyclopropyl cyanide, allyl cyanide, methacrylonitrile, and pyrrole rearrange to one common radical cation, most likely that of pyrrole [4].

Ion series: Consecutive maxima corresponding to C_nH_{2n-1} (m/z 41, 55, 69, 83, ...), accompanied by alkyl and alkenyl ions of the type C_nH_{2n+1} (m/z 43, 57, 71, 85, ...) and C_nH_{2n} (m/z 42, 56, 70, 84, ...), mostly of lower intensity.

Intensities: Dominant peaks in the low mass range, peaking around C₄. Local even-mass maxima due to alkene eliminations if the resulting double bond is highly substituted.

Molecular ion: Significant, but not necessarily strong.

Saturated Monocyclic Alicyclics [5]

Fragmentation: Preferred primary fragmentation by bond cleavage at branched C atoms, followed by loss of alkyl residues and alkenes.

Ion series: Consecutive maxima corresponding to C_nH_{2n-1} (m/z 41, 55, 69, 83, ...), accompanied by C_nH_{2n+1} (m/z 43, 57, 71, 85, ...) and C_nH_{2n} (m/z 42, 56, 70, 84, ...) of lower intensities. In general, the maxima are so similar to those of alkenes that no clear distinction is possible.

Intensities: Overall distribution of peaks maximizing in the lower mass range, around C₄ or C₅. Local maxima can result from branching effects.

Molecular ion: Significant, mostly of medium intensity.

Polycyclic Alicyclics

Fragmentation: Most important primary cleavage at highly branched carbon atoms, followed by H rearrangements and complex fragmentations.

Ion series: With increasing number of rings, the position of unsaturated hydrocarbon fragments in the upper m/z range shifts from C_nH_{2n-1} (m/z 41, 55, 69, 83, ...) to C_nH_{2n-3} (m/z 39, 53, 67, 81, ...) and to C_nH_{2n-5} (m/z 51, 65, 79, 93, ...). Typically, maxima in the lower m/z range have a lower degree of unsaturation than those in the upper m/z range.

Intensities: Major maxima evenly distributed, somewhat more intensive in the high mass or M^+ range.

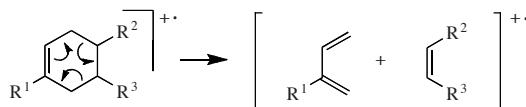

Molecular ion: Strong.

Cyclohexenes

Fragmentation: Loss of larger ring substituents as well as retro-Diels–Alder reaction, yielding fragments of even-mass maxima with one or two double-bond equivalents, C_nH_{2n} (m/z 42, 56, 70, 84, ...) and C_nH_{2n-2} (m/z 40, 54, 68, 82, ...), unless the retro-Diels–Alder product corresponds to ethylene. Somewhat unexpectedly, the base peak of cyclohexene is at $[M-15]^+$.

The retro-Diels–Alder reaction often accounts for prominent fragments of cyclohexenes and 1,4-cyclohexadienes:

However, double-bond migration may or may not occur beforehand. Also, other fragmentation pathways may dominate. Therefore, a reliable localization of the double bond in cyclohexene derivatives of unknown structure is not necessarily possible. For example, the base peak of 1,2-dimethylcyclohexene is at m/z 68 rather than at the expected m/z 82.

Ion series: Unsaturated hydrocarbon fragments in the upper m/z range are shifted, relative to cyclohexane fragments, by two mass units to C_nH_{2n-3} (m/z 39, 53, 67, 81, ...). Typically, maxima in the lower m/z range correspond to a lower degree of unsaturation than those in the upper m/z range.

Intensities: Intensive peaks evenly distributed over whole mass range.

Molecular ion: Medium intensity (ca. 40% in cyclohexene).

8.5 Aromatic Hydrocarbons [1–4]

Aromatic Hydrocarbons

Fragmentation: Weak tendency of fragmentation. Elimination of H⁺ and successive H₂ eliminations, yielding [M-1]⁺, [M-3]⁺, and [M-5]⁺ of decreasing intensities. In condensed aromatics, [M-2]⁺ can be a dominating fragment. Further typical fragmentation reactions are the eliminations of acetylene (Δm 26) and C₃H₃ (Δm 39). Some CH₃ elimination frequently occurs in pure aromatic compounds. In the case of diphenyl compounds, biphenylene (m/z 152) and, if a CH₂ group is available, fluorene (m/z 165) ions are typically observed.

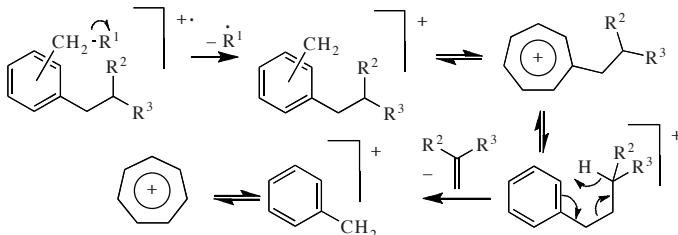

Ion series: C_nH_n and C_nH_{n±1} (m/z 39, 51–53, 63–65, 75–77, ...), for polycyclic aromatics gradually changing to more highly unsaturated ions. Doubly charged ions occur frequently, in particular as the size of the π-electron system increases.

Intensities: Weak fragments. The intensity pattern of doubly charged ions does not follow that of the corresponding singly charged ions.

Molecular ion: Strong.

Alkylsubstituted Aromatic Hydrocarbons

Fragmentation: Dominant loss of alkyl residues by benzylic cleavage, followed by elimination of alkenes.

At low resolution, methylbenzyl and β-phenylethyl have the same mass as benzoyl (m/z 105). In contrast to benzoyl, dehydrogenation products (m/z 104, 103) as well as protonated benzene (m/z 79) are also present if m/z 105 is a hydrocarbon rest.

Ion series: Aromatic hydrocarbon fragments, C_nH_n and C_nH_{n±1} (m/z 39, 51–53, 63–65, 75–77, ...), in the lower mass range.

Intensities: Intensive peaks mainly in the higher mass range. Maxima by benzylic cleavage.

Molecular ion: Strong or medium.

8.6 Heteroaromatic Compounds [1,2]

General Characteristics

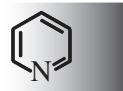

Fragmentation: Mostly fragments of aromatic character with specific eliminations including heteroatoms, e.g., elimination of HCN, CO, CHO, CS, and CHS from M^+ , and of HCN, CO, and CS from fragments. In the case of alkyl-substituted heteroaromatics, occurrence of benzylic-type cleavage and McLafferty rearrangements of substituents with $C_{n>1}$ as well as specific rearrangements including heteroatoms, especially in N aromatics.

Ion series: Aromatic fragments, C_nH_n and $C_nH_{n\pm1}$ (m/z 39, 51–53, 63–65, ...), in the lower mass range if the necessary number of C atoms is present (no such fragments, e.g., in pyrazine). Ions including heteroatoms like HCN^+ (m/z 27), CH_3CNH^+ (m/z 42), and CS^+ (m/z 44).

Intensities: Intensive peaks mainly in the higher mass range.

Molecular ion: Generally strong. $[M-1]^+$ is often relevant in alkyl-substituted heteroaromatics.

Furans [3]

Fragmentation: Oxygen can be lost from M^+ together with the neighboring C as CHO (Δm 29). In 2- or 6-methylfurans, CH_3CO^+ (m/z 43) can be seen (base peak in 2,5-dimethylfuran). As in aromatic methyl ethers, $[M-43]^+$ is a product of a two-step reaction: ($M^+ - CH_3 - CO$). Furans substituted with an alkyl group ($C_{n>1}$): benzylic-type cleavage (to pyrylium ion, $C_5H_5O^+$, m/z 81), followed by loss of CO.

Ion series: Mainly aromatic hydrocarbon fragments, C_nH_n and $C_nH_{n\pm1}$ (m/z 39, 51–53, 63–65, ...).

Intensities: Intensive peaks mainly in the higher mass range. The fragments are usually more important than in purely aromatic hydrocarbons.

Molecular ion: Strong. No pronounced tendency to protonate. Usually, $[M-1]^+$ is very strong in methylfurans.

Thiophenes [4]

Fragmentation: Sulfur can be lost from M^+ together with the neighboring C as CHS (Δm 45) or CS (Δm 44). Typical for thiophenes substituted with an alkyl group ($C_{n>1}$) is benzylic-type cleavage followed by loss of CS (Δm 44). Protonated thiophene (m/z 85) is a characteristic product of monoalkylated thiophenes.

Ion series: Aromatic hydrocarbon fragments, C_nH_n and $C_nH_{n\pm1}$ (m/z 39, 51–53, 63–65, ...). Besides the isotope peak at $[M+2]^+$, the signals at m/z 44 and 45 (CS⁺ and CHS⁺) are indicators of sulfur.

Intensities: Dominant peaks for M^+ and products of benzylic-type cleavage.

Molecular ion: Strong. Characteristic S isotope signal ($[M+2]^+$ corresponds to 4.5% of M^+). No pronounced tendency of protonation. Usually, $[M-1]^+$ is very strong in methylthiophenes.

Pyrroles [5]

Fragmentation: HCN elimination ($\Delta m 27$) from M^{+} and from fragments. In methylpyrroles, $[M-1]^{+}$ is dominant. Benzylic-type cleavage in C- and N-alkyl-pyrroles with or without (nonspecific) H rearrangements.

Ion series: Aromatic hydrocarbon fragments, C_nH_n and $C_nH_{n\pm 1}$ (m/z 39, 51–53, 63–65, ...).

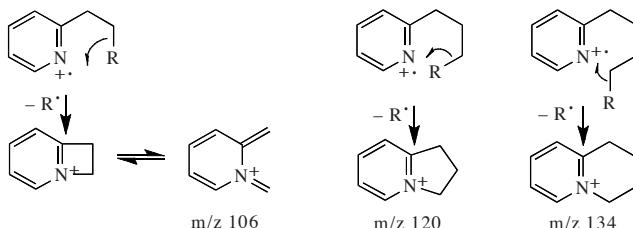

Intensities: Dominant peaks for M^{+} and products of benzylic-type cleavage.

Molecular ion: Strong (odd mass for odd number of N in the molecule). No tendency to protonate. In methyl-substituted pyrroles, $[M-1]^{+}$ is dominant.

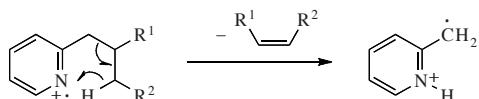

Pyridines

Fragmentation: HCN elimination ($\Delta m 27$) from fragments and the ion H_2CN^{+} (m/z 28) are characteristic. Additional reactions in 2- or 6-methylpyridines are CH_3CN elimination ($\Delta m 41$) and the formation of CH_3CNH^{+} (m/z 42). Benzylic cleavage is dominant for 3-alkyl-, strong for 4-alkyl-, and weak for 2-alkylpyridines. Typical rearrangements with participation of the N atom in 2- and 6-alkylpyridine derivatives.

Intramolecular N-alkylation in 2-alkyl derivatives:

McLafferty rearrangements are important in 2- and 4-alkylpyridines:

Ion series: Aromatic hydrocarbon fragments, C_nH_n , $C_nH_{n\pm 1}$ and $C_nH_{n\pm 1}N$ (m/z 39–41, 51–54, 63–67, 75–80, ...).

Intensities: Dominant peaks for M^{+} or, if possible, for products of benzylic-type cleavage.

Molecular ion: Strong, except when benzylic-type cleavage is possible. Odd mass for an odd number of N in the molecule. No tendency to protonate. $[M-1]^{+}$ is usually present and is strong in alkyl-substituted pyridines.

N-Oxides of Pyridines and Quinolines

Fragmentation: The $[M-O]^{+}$ radical ion, of variable intensity, is probably due to thermal decomposition. The fragments $[M-CO]^{+}$ and, if an alkyl group is present on the neighboring C atom, $[M-OH]^{+}$ are relevant for quinoline N-oxides. Rearrangements with ring formation including the N–O moiety if alkyl or aryl groups

are present in the neighboring positions.

Ion series: As for the corresponding heteroaromatics, aromatic hydrocarbon fragments, C_nH_n , $C_nH_{n\pm 1}$ and $C_nH_{n\pm 1}N$ (m/z 39–41, 51–54, 63–67, 75–80, ...), are observed.

Intensities: Dominant peaks for M^+ and products of benzylic-type cleavage.

Molecular ion: Strong, except when $[M-O]^+$ dominates due to experimental conditions or when benzylic-type cleavage is possible. Odd mass for odd number of N atoms in the molecule. No tendency to protonate.

Pyridazines and Pyrimidines

Fragmentation: Loss of N_2 or CH_2N^- (Δm 28) from pyridazines. Also, loss of N_2H^- (especially important in methylpyridazines) to give $[M-29]^+$. In pyridazine N-oxides, consecutive loss of NO^- and HCN . Consecutive losses of two HCN ($2 \times \Delta m$ 27) molecules from pyrimidines. From 2-, 4-, and 6-methylpyrimidines, CH_3CN (Δm 41) is eliminated and the ion CH_3CNH^+ (m/z 42) occurs.

Ion series: Aromatic hydrocarbon fragments (C_nH_n , $C_nH_{n\pm 1}$) and, for pyrimidines, $C_nH_{n\pm 1}N$, at low masses (m/z 39, 51–53).

Intensities: Dominant peak for M^+ .

Molecular ion: Strong. No tendency to protonate. For pyrimidines, $[M-1]^+$ is usually observable.

Pyrazines

Fragmentation: Consecutive losses of two HCN ($2 \times \Delta m$ 27) molecules. For methylpyrazines, elimination of CH_3CN (Δm 41) and formation of CH_3CNH^+ (m/z 42).

Ion series: No aromatic character of the spectra.

Intensities: Dominant peak for M^+ .

Molecular ion: Strong. No tendency to protonate. Usually, $[M-1]^+$ is observable; it can be stronger than M^+ in alkyl-substituted ($C_{n>1}$) pyrazines.

Indoles

Fragmentation: Analogous to pyrrole; HCN elimination (Δm 27) from M^+ and from fragments. From M^+ also CH_2N^- (Δm 28) elimination (in one or two steps). In methyl-substituted indoles, $[M-1]^+$ is dominant. In *N*-methylindoles, $[M-15]^+$ is significant. Benzylic-type cleavage in *C*- and *N*-alkylindoles with or without (non-specific) H rearrangements.

Ion series: Aromatic ion series.

Intensities: Dominant maxima in the higher mass range.

Molecular ion: Strong. No tendency to protonate. In methyl-substituted indoles, strong signal for $[M-1]^+$.

Quinolines and Isoquinolines

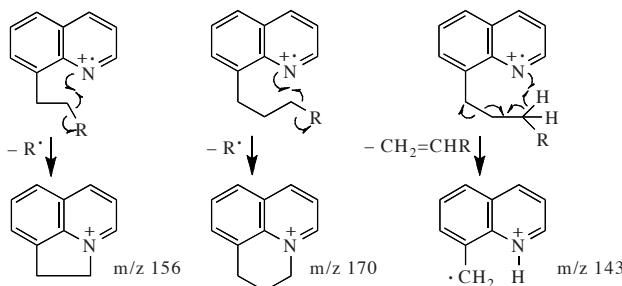

Fragmentation: Similar to pyridine: HCN elimination ($\Delta m 27$) from M^+ , $[M-1]^+$, and fragments. In methylquinolines and methylisoquinolines also CH_3CN elimination ($\Delta m 41$). In alkyl-substituted ($C_{n>1}$) quinolines, benzylic cleavage dominates except when neighboring effects of N play a role. For 2- and 8-alkylquinolines as well as 1- and 3-alkylisoquinolines, see rearrangements in pyridines.

Ion series: Aromatic hydrocarbon fragments, C_nH_n , $C_nH_{n\pm 1}$, and $C_nH_{n\pm 1}N$ ($m/z 39-41, 51-54, 63-67, 75-80, \dots$).

Intensities: Dominant peak for M^+ or, if possible, for products of benzylic-type cleavage.

Molecular ion: Strong, except when benzylic-type cleavage is possible. Odd mass for odd number of N atoms in the molecule. No tendency to protonate. $[M-1]^+$ is usually present and is strong in alkyl-substituted quinolines.

Rearrangements in 8-alkylquinolines:

Cinnoline, Phthalazine, Quinazoline, Quinoxaline

Fragmentation: Same as for the corresponding monocyclic heteroaromatics pyridazine, pyrimidine, and pyrazine. Characteristic for pyridazine, cinnoline, and phthalazine is the elimination of N_2 ($\Delta m 28$) and N_2H^+ ($\Delta m 29$) from their alkyl derivatives. Phthalazine loses HCN ($\Delta m 27$) twice.

Ion series: Aromatic hydrocarbon fragments, (C_nH_n , $C_nH_{n\pm 1}$) and $C_nH_{n\pm 1}N$ ($m/z 39-41, 51-54, 63-67, 75-80, \dots$).

Intensities: Dominant maximum for M^+ or, if possible, for products of benzylic-type cleavage.

Molecular ion: Strong, except when benzylic-type cleavage is possible. Odd mass for odd number of N atoms in the molecule. No tendency to protonate. $[M-1]^+$ is usually present and is strong in alkyl-substituted compounds.

8.7 Halogen Compounds [1–3]

Saturated Aliphatic Halides

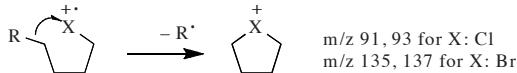

Fragmentation: Loss of halogen radical ($I > Br > Cl > F$) followed by elimination of alkenes. Loss of alkyl radical followed by elimination of acid HX . Loss of acid HX to give an alkene radical cation.

Ion series: The dominant hydrocarbon fragments are mainly alkenyl fragments (C_nH_{2n-1}) for F and Cl, mixed alkyl (C_nH_{2n+1}) and alkenyl fragments (C_nH_{2n-1}) for Br, and mainly alkyl fragments (C_nH_{2n+1}) for I.

Hal

Intensities: Intensive peaks mainly in the lower mass range. Characteristic maxima for Cl and Br at $C_4H_8X^+$ (m/z 91, 93 and 135, 137, respectively), which has a cyclic structure:

Alkyl substituents on the chain reduce the intensity of this fragment. If it is strong, $[M-X]^+$ is weak. In the case of iodoalkanes, some I^+ and HI^+ at m/z 127, 128 is usually detectable.

Molecular ion: Strong for the smallest alkanes, with increasing intensity in the sequence F, Cl, Br, I. Decreases rapidly with increasing mass and with increasing branching. It is negligible for F and Cl if the n -alkyl chains are longer than pentyl, and for Br and I if they are longer than heptyl and nonyl, respectively. Low tendency to protonate. Characteristic isotope patterns for Cl and Br. Iodine can be detected because of its high mass; the ^{13}C signals of M^{+} and its fragments are conspicuously weak.

Polyhaloalkanes

Fragmentation: Preferred fragmentation of the C–C bond if several halogen atoms are bonded to one of these carbon atoms. CF_3 (m/z 69) is often the base peak in terminally perfluorinated alkanes, and so is $CHCl_2$ (m/z 83, 85, 87) in terminally dichlorinated compounds. Often, X_2 is eliminated besides the usual fragmentation of X and HX . Interchange of halogens may occur. For example, m/z 85 (CF_2Cl) is a dominant signal (ca. 60%) for CF_3CFCl_2 .

Ion series: Most fragments are halogenated alkyl and alkenyl groups, easily detectable on the basis of the isotope signals in the cases of Cl and Br.

Intensities: Intensive peaks mainly in the lower mass range.

Molecular ion: Weak, decreasing with increasing number of halogen atoms. Absent from the spectra of many polyhalogenated compounds.

Aromatic Halides

Fragmentation: Consecutive losses of halogen radicals and/or acid HX. In perhalogenated aromatics, decomposition down to C_x^+ , with x from 1 to 6 (m/z 12, 24, 36, 48, 60, 72). If alkyl-substituted ($C_{n>1}$), the base peak is mostly the result of benzylic cleavage. In an otherwise aromatic environment, m/z 57 is a F indicator ($C_3H_2F^+$). Elimination of CF_2 (Δm 50) from CF_3 groups attached to the aromatic ring (from M^+ or fragments).

Ion series: Aromatic fragments, C_nH_n , C_nH_{n-1} , and C_nH_{n-2} (m/z 39, 51–53, 63–65, 75–77, ...). In the higher mass range: $C_n(H,X)_n$.

Intensities: Dominant peaks in the M^+ region.

Molecular ion: Usually very strong. Characteristic isotope signals for Cl and Br.

Hal

8.8 Alcohols, Ethers, and Related Compounds [1,2]

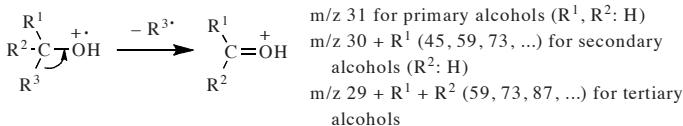

8.8.1 Alcohols and Phenols

Aliphatic Alcohols [3]

Fragmentation: Elimination of water from M^{+} and from fragments. Strong for primary alcohols. If an aliphatic H atom can be transferred in a 6-ring process, it is involved in the water elimination in 90% of the investigated cases. If a CH_2CH_2 group is attached to the O-bearing C atom, water elimination is often followed by loss of ethylene. Water elimination is dominant for long-chain alcohols, rendering their spectra similar to those of alkenes.

Cleavage of bonds next to the OH-bearing C atom to form oxonium ions, then elimination of water and of alkenes. The α -cleavage is often dominant. Usually, its importance increases with increasing branching at the α -carbon atom. The larger substituent is lost most readily.

O

Consecutive H_2O and alkene eliminations in longer-chain primary alcohols lead to $[M-46]^{+}$, $[M-74]^{+}$, $[M-102]^{+}$, ... In particular, branched alcohols frequently show a typical series of fragments at $[M-15]^{+}$, $[M-18]^{+}$, and $[M-33]^{+}$.

Ion series: Dominant alkene ions corresponding to C_nH_{2n-1} ($m/z\ 41, 55, 69, \dots$), C_nH_{2n} ($m/z\ 42, 56, 70, \dots$), accompanied by weaker fragments, $C_nH_{2n+1}O$ ($m/z\ 31, 45, 59, \dots$), with one or more local maxima in the latter series ($m/z\ 31$ dominates in primary alcohols).

Intensities: Intensive peaks in the lower mass range, local maxima among alkene-type fragment ions of the type $C_nH_{2n+1}O^{+}$.

Molecular ion: Mostly weak, often missing, especially in tertiary and long-chain alcohols. Indirect determination of M^{+} is often possible from the fragments at $[M-15]^{+}$, $[M-18]^{+}$ and $[M-33]^{+}$. $[M+1]^{+}$ is often significant. In primary and secondary alcohols also $[M-1]^{+}$ can usually be seen. Sometimes, $[M-2]^{+}$ is formed because of oxidation to carbonyl compounds during sample introduction.

Alicyclic Alcohols

Fragmentation: Elimination of water from M^{+} , followed by loss of alkyl or alkenyl residues. Ring cleavage at the O-bearing C atom, followed by loss of alkyl residues after H rearrangement (see scheme).

Ion series: Alkene hydrocarbon fragments C_nH_{2n-1} ($m/z\ 41, 55, 69, \dots$), C_nH_{2n-3} ($m/z\ 39, 53, 67, 81, \dots$), and unsaturated O fragments, $C_nH_{2n-1}O$ ($m/z\ 43, 57, 71, \dots$), as well as acetaldehyde and its homologues ($m/z\ 44, 58, 72, \dots$).

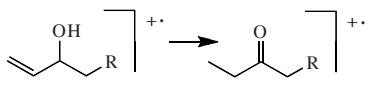

Intensities: Local maxima evenly distributed over the whole mass range.

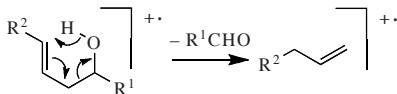

Molecular ion: Usually weak but in contrast to aliphatic alcohols practically never missing. $[M+1]^+$ typically contains a significant amount of $[M+H]^+$.

Unsaturated Aliphatic Alcohols [3]

Allyl alcohols: The spectra are similar to those of the corresponding carbonyl compounds, which are (partly) formed by double H rearrangement of M^+ .

γ,δ -Unsaturated alcohols: Aldehyde elimination through a McLafferty-type rearrangement.

Vicinal Glycols

Fragmentation: Cleavage of bonds next to the OH-bearing C atom (α -cleavage) dominates. Preferable fragmentation of the C–C bond between the two oxygens, the charge remaining predominantly on the larger fragment. Water elimination from these fragments, but scarcely from M^+ .

O

Ion series: Saturated and unsaturated aliphatic ions (m/z 43, 57, 71, ... and 41, 55, 69, ...) and intensive peaks from O-containing saturated rests (m/z 45, 59, 73, ...).

Intensities: Dominant peaks for the products of α -cleavages and their dehydrated derivatives.

Molecular ion: Weak.

Phenols

Fragmentation: Decarbonylation (Δm 28) and loss of CHO^\cdot (Δm 29) followed by elimination of acetylene. An important fragment of alkyl derivatives is $[M-1]^+$, as is $[M-15]^+$ if at least two alkyl carbons are present (dimethyl or ethyl). Elimination of CO from the primary fragments. $[M-18]^+$ mainly with *ortho*-alkylphenols. In derivatives with a longer alkyl chain, benzylic cleavage and alkene elimination (McLafferty rearrangement) are the dominant primary fragmentation processes. The fragments then lose CO (Δm 28).

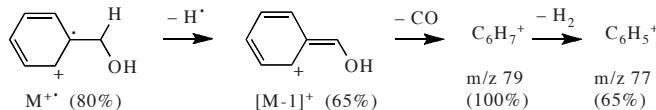

Ion series: Aromatic hydrocarbon fragments, C_nH_n and $C_nH_{n\pm 1}$ (m/z 39, 51–53, 63–65, 75–77, ...). The presence of some m/z 55 (C_3H_3O) is common. A peak at m/z 69 ($O=CCH=C=O$) is characteristic of 1,3-dihydroxy substitution.

Intensities: Dominant peaks in the higher mass range.

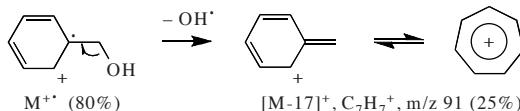

Molecular ion: Dominant, no tendency to form $[M+H]^+$; $[M-1]^+$ is weak.

Benzyl Alcohols

Fragmentation: Loss of H⁺ and consecutive elimination of CO (Δm 28) to give a protonated benzene molecule, which further loses H₂.

Elimination of OH⁻ (Δm 17) to yield the tropyl cation is the second important fragmentation path:

Ion series: Aromatic fragments corresponding to C_nH_n and C_nH_{n±1} (m/z 39, 51–53, 63–65, 75–77, ...).

Intensities: Dominant peaks for the products described under *Fragmentation*. For benzyl alcohol decreasing in the sequence of [M-29]⁺, M⁺, [M-1]⁺, [M-31]⁺, [M-17]⁺.

Molecular ion: Strong.

8.8.2 Hydroperoxides

O

Aliphatic Hydroperoxides [4]

Fragmentation: Most pronounced is the loss of the hydroperoxy radical HO₂[·] (Δm 33), especially when a tertiary alkyl cation is formed. Important, in decreasing order, is loss of H₂O₂ (Δm 34), H₂O (Δm 18), HO[·] (Δm 17), and O (Δm 16).

Ion series: Mainly saturated and unsaturated alkyl fragments, C_nH_{2n+1} (m/z 43, 57, 71, ...) and C_nH_{2n-1} (m/z 41, 55, 69, ...). The oxygen-indicating fragment at m/z 31 and its homologues are always present.

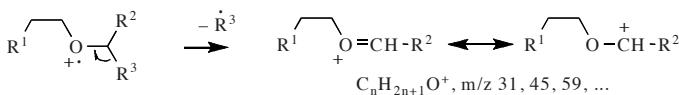

Intensities: Intensive peaks mainly in the lower mass range.

Molecular ion: Weak.

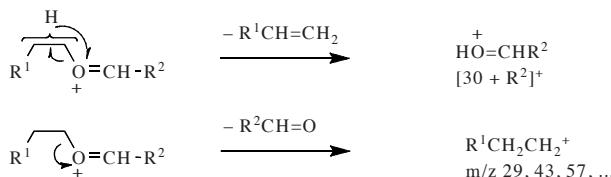

8.8.3 Ethers

Aliphatic Ethers [5,6]

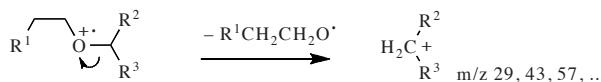

Fragmentation: Homolysis of the C–C bond next to the O atom to yield oxygen-containing fragments. Preferably, the bond at the highest substituted C atom breaks and the larger alkyl group is lost.

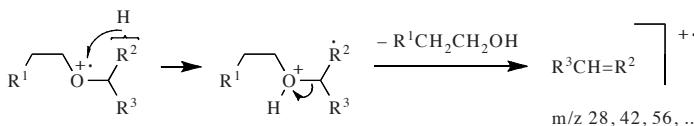

This homolysis is followed by the elimination of alkenes, aldehydes, or, less importantly, of water.

As a competing process, especially with increasing molecular weight, heterolysis at the O atom takes place to yield strong alkyl ion signals. The larger as well as the branched alkyl rests are fragmented preferably. The base peak often arises from heterolysis of the C–O bond.

In contrast to the H_2O elimination from alcohols, the H transfer involved in the elimination of $\text{RCH}_2\text{CH}_2\text{OH}$ from ethers is nonspecific.

Ion series: Alkyl fragments, $\text{C}_n\text{H}_{2n+1}$ ($\text{m/z } 29, 43, 57, \dots$), with maxima due to cleavage of the C–O bond. Alkene ion series, C_nH_{2n} ($\text{m/z } 28, 42, 56, \dots$), due to elimination of alcohol. Oxygen-containing fragments, $\text{C}_n\text{H}_{2n+1}\text{O}$ ($\text{m/z } 31, 45, 59, \dots$), with maxima due to cleavage of the C–C bond next to the oxygen.

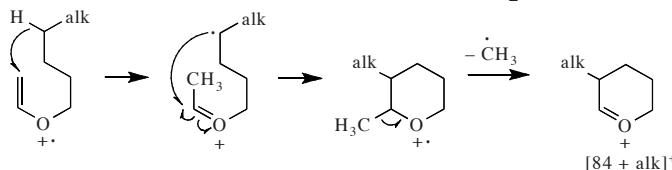

Intensities: Intensive peaks mainly in the lower mass range.

Molecular ion: Significant or weak. Decreasing with increasing chain length and branching.

O

Unsaturated Ethers [7]

Fragmentation of vinylic and acetylenic alkyl ethers: Dominant homolysis of the alkyl C–C bond next to the O atom on the saturated side, leading to $\text{C}_3\text{H}_5\text{O}^+$ ($\text{m/z } 57$) for vinylic and $\text{C}_3\text{H}_3\text{O}^+$ ($\text{m/z } 55$) for acetylenic ethers of primary aliphatic alcohols. For alkyl ($\text{C}_{n>5}$) vinyl ethers, ethanol elimination after triple H transfer. $[\text{M}-15]^+$ in vinyl ethers predominantly by elimination of the vinyl CH_2 after H rearrangement.

Fragmentation of allylic ethers: Heterolysis of both C–O bonds, leading to strong C_3H_5^+ ($\text{m/z } 41$) and alkyl ($\text{m/z } 29, 43, 57, \dots$) cations. Formation of ionized allyl alcohol ($\text{C}_3\text{H}_6\text{O}^+$, $\text{m/z } 58$) by nonspecific H transfer from the alkyl rest. In allylic

and propargylic ethers, no cleavage of the C–C bond next to the O atom of the alk-enyl group occurs. Hence, loss of vinyl or acetylenyl cannot be observed.

Ion series: $C_nH_{2n}O$ (m/z 44, 58, 72, ...) for alkenyl alkyl ethers and $C_nH_{2n-2}O$ (m/z 42, 56, 70, ...) for dialkenyl ethers. Unsaturated aliphatic (C_nH_{2n-1} ; m/z 41, 55, 69, ...) as well as saturated aliphatic and unsaturated oxygen-containing fragments (C_nH_{2n+1} and $C_nH_{2n-1}O$; m/z 43, 57, 71, ...).

Intensities: Intensive peaks mainly in the lower mass range.

Molecular ion: Weak to medium, very weak for acetylenic ethers.

Alkyl Cycloalkyl Ethers

Fragmentation of methyl ethers of cycloalkanols with > 3 C atoms: After primary cleavage of the ring C–C bond next to the O atom, the prominent fragments formed are $CH_3OCH=CH_2^+$ (m/z 58) and, for alicyclics with > 4 C atoms, $CH_3O=CHCH=CH_2^+$ (m/z 71, rearrangement in analogy to that observed for cycloalkanols). Loss of methanol to give hydrocarbon fragments, C_nH_{2n-2} (m/z 54, 68, 82, ...).

Fragmentation of ethyl and higher alkyl ethers of cycloalkanols with > 3 C atoms: Alkene elimination to yield the protonated cycloalkanol (m/z 72, 86, 100, ...) and heterolytic cleavage of the C–O bond to give dominating cycloalkyl ions (m/z 69, 83, ...).

Ion series: Besides the fragments already mentioned, mainly unsaturated hydrocarbon fragments (C_nH_{2n-1} , m/z 27, 41, 55, 69, ...).

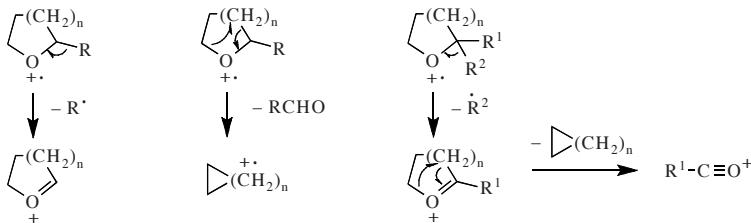

Intensities: The above mentioned fragments dominate the spectrum.

Molecular ion: Weak or intermediate.

O

Cyclic Ethers

Fragmentation: Primary ring cleavage at C–C bonds next to the O atom, followed by loss of CH_2O ($\Delta m 30$), H_2O ($\Delta m 18$), or alkyl ($\Delta m 15, 29, \dots$). Elimination of H^+ to give $[M-1]^+$, followed by CO elimination ($\Delta m 28$) to $[M-29]^+$. When α -substituted, dominant loss of substituents, followed by water elimination. Formation of acyl cation if two α -substituents are present.

Ion series: Mainly ions of the alkene type. Weak saturated, oxygen-containing fragments (m/z 31, 45, ...).

Intensities: Intensive peaks evenly distributed over the whole mass range.

Molecular ion: Often significant but sometimes weak, especially when α -substituted. Intensity of $[M-1]^+$ usually comparable to that of M^+ if no α substituent is present.

Methoxybenzenes

Fragmentation: Loss of methyl radical, followed by decarbonylation to $[M-43]^+$; elimination of formaldehyde ($\Delta m 30$) from M^+ or from primary fragments.

Ion series: Aromatic fragments corresponding to C_nH_n and $C_nH_{n\pm 1}$ (m/z 39, 51–53, 63–65, 75–77, ...).

Intensities: Intensive peaks in the M^+ region.

Molecular ion: Strong.

Alkyl Aryl Ethers [8]

Fragmentation: Commonly dominating alkene elimination to give the corresponding phenol ion (nonspecific hydrogen migration), followed by decarbonylation. In the case of aryl methyl ethers, loss of CH_2O from M^+ or from primary fragments as well as CH_3^+ elimination followed by decarbonylation.

Ion series: Mostly aromatic fragments, C_nH_n and $C_nH_{n\pm 1}$ (m/z 39, 51–53, 63–65, 75–77, ...).

Intensities: Usually maximum at the mass of the corresponding phenol. Otherwise, intensive peaks mainly concentrated in the high and medium mass range.

Molecular ion: Strong.

Aromatic Ethers

Fragmentation: Loss of H^+ ($\Delta m 1$), CO ($\Delta m 28$), and CHO^+ ($\Delta m 29$) from M^+ . Cleavage at the C–O bond and decarbonylation of the resulting product, followed by dehydrogenation.

Ion series: Aromatic fragments corresponding to C_nH_n and $C_nH_{n\pm 1}$ (m/z 39, 51–53, 63–65, 75–77, ...).

Intensities: Intensive peaks mainly in the M^+ region.

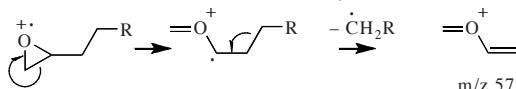

Molecular ion: Strong.

O

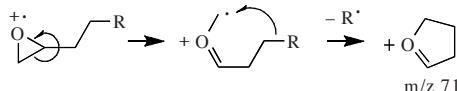

8.8.4 Aliphatic Epoxides [9]

Fragmentation: The most important primary fragmentation is the cleavage of C–C bonds next to the O atom (α -cleavage), resulting in complex degradation due to the related multiple choice and extensive secondary rearrangements. The products allow mass-spectrometric localization of double bonds after epoxidation.

Due to ring opening prior to fragmentation, β -cleavage is as relevant as the α -cleavage.

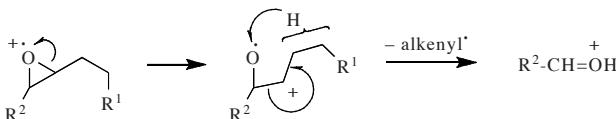

γ -Cleavage is the most important fragmentation mechanism, especially in terminal epoxides:

Mainly in terminal epoxides, rearrangement with alkene elimination, formally leading to alkene-OH⁺ ($C_nH_{2n}O$, m/z 44, 58, 72, ...) and alkene⁺ (C_nH_{2n} , m/z 28, 42, 56, ...):

Mainly in nonterminal epoxides, transannular cleavage with H transfer and elimination of an alkenyl radical, leading to $C_nH_{2n+1}O$ fragments (m/z 45, 59, 73, ...):

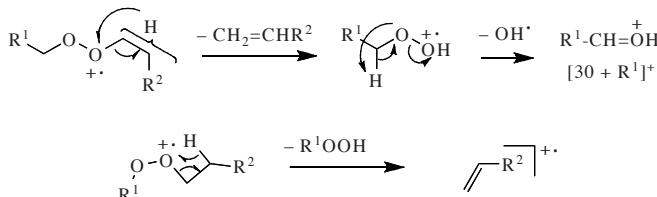

Ion series: Mixed, not characteristic.

Intensities: Intensive peaks mainly in the lower mass range.

Molecular ion: Usually weak.

8.8.5 Aliphatic Peroxides [4]

O *Fragmentation:* Alkene elimination to give hydroperoxide radical cations and hydroperoxide elimination to yield alkene radical cations (dominating if larger alkyl groups are present). Alkene elimination can be followed by loss of OH[·], resulting in products that formally correspond to those obtained by O–O cleavage, which probably is not a one-step process:

Elimination of O[·] or O₂ may occur in cyclic peroxides. *tert*-Butyl peroxides predominantly eliminate *tert*-butyl-OO[·] to give [M-89]⁺.

Ion series: Saturated or unsaturated alkyl groups (C_nH_{2n+1} , m/z 29, 43, 57, ...; C_nH_{2n-1} , m/z 27, 41, 55, ...) and alkenyl ions (C_nH_{2n} , m/z 28, 42, 56, ...) dominate. The fragment at m/z 31 and sometimes its homologues indicate the presence of oxygen.

Intensities: Intensive peaks mainly in the lower mass range.

Molecular ion: Weak to moderate.

8.9 Nitrogen Compounds [1,2]

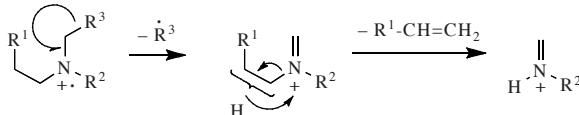

8.9.1 Amines

Saturated Aliphatic Amines [3]

Fragmentation: Dominating loss of alkyl residues by cleavage of the C–C bond next to the N atom ("N-cleavage"). Larger substituents are eliminated preferably. When a γ -H is available, subsequent elimination of alkenes by McLafferty-type reactions:

Otherwise, unspecific H transfer onto the N atom:

NH_3 , RNH_2 , and $\text{RR}'\text{NH}$ eliminations from primary, secondary, and tertiary amines, respectively, are negligible except from some multifunctional compounds (e.g., diamines and phenyl-phenoxy-substituted amines).

Ion series: Even-mass fragments of the type $\text{C}_n\text{H}_{2n+2}\text{N}$ (m/z 30, 44, 58, 72, 86, ...).

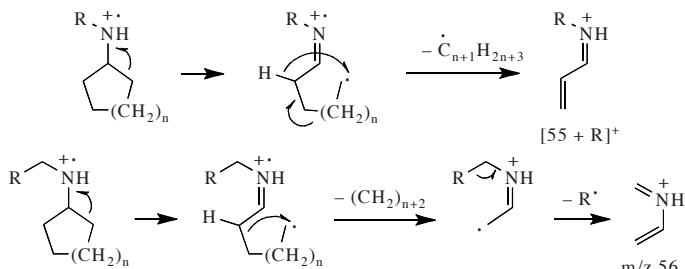

Intensities: Mainly peaks in the low mass range. Dominating base peak from "N-cleavage" at $[28 + m(\text{R}^1) + m(\text{R}^2) + m(\text{R}^4) + m(\text{R}^5)]^+$ for $\text{R}^1\text{R}^2\text{R}^3\text{CNR}^4\text{R}^5$ (e.g., m/z 30 for RCH_2NH_2 , m/z 44 for $\text{RCH}_2\text{NHCH}_3$, m/z 58 for $\text{RCH}_2\text{N}(\text{CH}_3)_2$, and m/z 86 for $\text{RCH}_2\text{N}(\text{CH}_2\text{CH}_3)_2$). Local maximum at m/z 86 ($\text{C}_5\text{H}_{12}\text{N}^+$) for n -alk-NH₂ (protonated piperidine, 6-membered ring).

Molecular ion: Usually weak or absent, especially if the α -C atom is substituted. Decreasing intensity with increasing molecular weight. Tendency to protonate to $[\text{M}+\text{H}]^+$. Odd mass for odd number of N atoms in the molecule.

N

Cycloalkylamines

Fragmentation: The most important primary reaction is the ring cleavage next to the N atom, followed by H rearrangement and loss of an alkyl residue. Some elimination of amine, $\text{R}^1\text{R}^2\text{NH}$.

Ion series: Even-mass fragments of the type $C_nH_{2n}N$ (m/z 42, 56, 70, 84, ...).

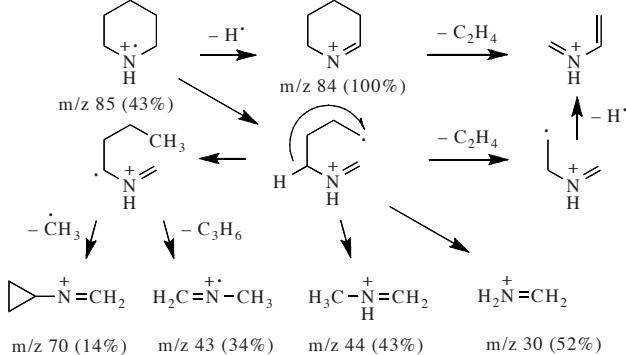

Intensities: Intensive local maxima evenly distributed over the whole mass range.

Molecular ion: Usually significant. Odd mass for odd number of N atoms in the molecule.

Cyclic Amines

Fragmentation: Dominating primary reaction is the cleavage of C–C bonds next to N, resulting in the loss of substituents next to N or in primary ring cleavage. Primary ring cleavage is followed by H rearrangement and loss of alkenes or alkyl groups. The most important primary fragmentation for substituted cyclic amines is the loss of substituents at C atoms next to N.

Piperidine:

Ion series: Even-mass fragments of the type $C_nH_{2n}N$ (m/z 42, 56, 70, 84, ...) and $C_nH_{2n+2}N$ (m/z 30, 44, 58, ...) as well as odd-mass fragments of the type $C_nH_{2n+1}N$ (m/z 43, 57, 71, 85, ...).

Intensities: Intensive local maxima evenly distributed over the whole mass range if no substituent is bonded to the C atom next to N. Otherwise, dominating maxima by loss of such substituents.

Molecular ion: Significant or strong if no substituent is bonded to the C atom next to N; otherwise, weak. Tendency to form $[M-H]^+$. Odd mass for odd number of N atoms in the molecule.

N

Piperazines

Fragmentation: As for cyclic amines, enhanced primary ring cleavage at C–C bonds next to the N atom.

Ion series: Even-mass fragments of the type $C_nH_{2n}N$ (m/z 42, 56, 70, 84, ...) and $C_nH_{2n+2}N$ (m/z 30, 44, 58, ...) as well as odd-mass series of the type $C_nH_{2n+1}N$ (m/z 43, 57, 71, 85, ...).

Intensities: Intensive local maxima evenly distributed over the whole mass range if no substituent is bonded to the C atom next to N. Otherwise, dominating maxima by loss of such substituents.

Molecular ion: Significant or strong if no substituent is bonded to the C atom next to N; otherwise, weak. Tendency to form $[M-H]^+$. Odd mass for odd number of N atoms in the molecule.

Aromatic Amines

Fragmentation: Dominating cleavage of alkyl bond at N-bearing C atom (“N-cleavage”) followed by alkene elimination if aliphatic substituents with $C_{n \geq 2}$ are present. Otherwise, loss of H⁺ from primary and secondary anilines and benzylic amines. Loss of HCN from M⁺ or from fragments. A local maximum at m/z 42 is typical of an aromatically bonded dimethylamino group.

Ion series: Aromatic hydrocarbon fragments (C_nH_n and $C_nH_{n\pm 1}$; m/z 39, 51–53, 63–65, 75–77, ...).

Intensities: Dominating maxima by “N-cleavage” and following alkene loss if aliphatic substituents with $C_{n > 1}$ are present.

Molecular ion: Abundant if no aliphatic substituents with more than one C atom are present, otherwise, medium or weak. No tendency to protonate. In primary and secondary aromatic and benzylic amines, [M-H]⁺ is important. Odd mass for odd number of N atoms in the molecule.

8.9.2 Nitro Compounds

Aliphatic Nitro Compounds

Fragmentation: Loss of NO[·] (Δm 30), NO₂[·] (Δm 46), and HNO₂ (Δm 47) as well as the formation of some m/z 30 as N indicator. Spectra with only few characteristic features.

Ion series: Mixed alkyl and alkenyl fragments, C_nH_{2n+1} (m/z 43, 57, 71, ...) and C_nH_{2n-1} (m/z 41, 55, 69, ...).

Intensities: Dominant peaks in the lower mass range.

Molecular ion: Weak or missing. Odd mass for odd number of N atoms in the molecule.

N

Aromatic Nitro Compounds

Fragmentation: Loss of O (Δm 16), NO[·] (Δm 30, followed by elimination of CO, Δm 28), and NO₂[·] (Δm 46) from M⁺ or from a major primary cleavage product. Extensive rearrangement of the functional group to a nitroso ester.

Ion series: Aromatic fragments corresponding to C_nH_n and $C_nH_{n\pm 1}$ (m/z 39, 51–53, 63–65, 75–77, ...).

Intensities: Intensive peaks mainly in the upper mass range.

Molecular ion: Strong. Odd mass for odd number of N atoms in the molecule.

8.9.3 Diazo Compounds and Azobenzenes

Diazo Compounds [4,5]

Diazonium: Because of the low volatility of diazo compounds, their electron impact mass spectra show thermal decomposition products. These are formed by loss of N₂

(e.g., a diazonium chloride gives rise to the corresponding aromatic chloro compound). From a phenyl diazonium *ortho*-carboxylate zwitterion, biphenylene is formed as dimerization product.

Diazomethane and derivatives: M^{+} is strong except when catalytic decomposition occurs on metal surfaces of the inlet system. Loss of N_2 is a dominant reaction of diazomethane and diazoketones.

Azobenzenes

Fragmentation: Cleavage at the azo group followed by loss of N_2 , giving rise to the dominant base peak.

Ion series: Aromatic fragments (C_nH_n , $C_nH_{n\pm 1}$; m/z 39, 51–53, 63–65, 75–77, ...).

Intensities: Dominant M^{+} and azo cleavage products.

Molecular ion: Strong. Odd mass for odd number of N atoms in the molecule.

8.9.4 Azides

Aliphatic Azides [6]

Fragmentation: $[M-42]^{+}$ (N_3^- elimination) or $[M-28]^{+}$ (N_2 elimination) dominant in most cases. The spectra are similar to those of the corresponding aliphatic compounds.

Ion series: Aliphatic hydrocarbon series.

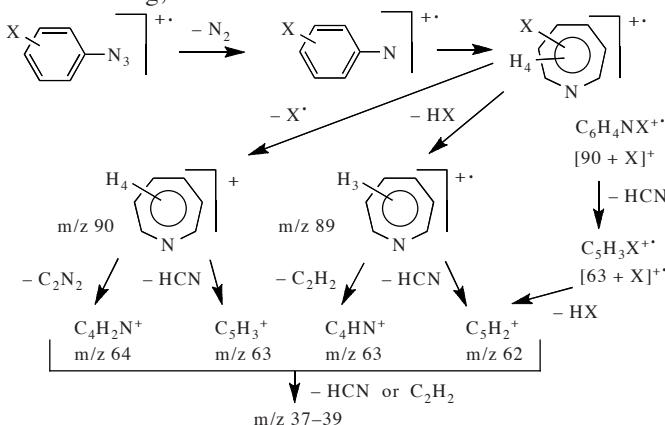

Intensities: Dominant peaks in the lower mass range, as in aliphatic compounds.

Molecular ion: Absent or weak. Odd mass for odd number of N atoms in the molecule.

Aromatic Azides [7]

N

Fragmentation: In most cases, $[M-28]^{+}$ (N_2 elimination) is the base peak. The next step is the elimination of HCN (Δm 27) or acetylene (Δm 26), or, if there is a substituent X on the ring, of X^{\cdot} or HX .

Ion series: Aromatic hydrocarbon fragments (C_nH_n and $C_nH_{n\pm 1}$; m/z 39, 51–53, 63–65, 75–77, ...).

Intensities: Dominant peaks in the higher mass range; $[M-28]^{+}$ (N_2 elimination) and $[M-55]^{+}$ (N_2 and HCN elimination) are the most intensive peaks.

Molecular ion: Weak. Odd mass for odd number of N atoms in the molecule.

8.9.5 Nitriles and Isonitriles

Aliphatic Nitriles ($R-CN$) [4]

Fragmentation: Elimination of alkyl radicals to give $(CH_2)_nCN^{+}$ (m/z 40, 54, 68, ...). McLafferty rearrangement yielding $CR_2=C=NH^{+}$ (m/z 41 for R: H). In most cases, C–CN cleavage and HCN elimination are not significant reactions. Complex rearrangements in unsaturated nitriles if other functional groups are present.

Ion series: Saturated and unsaturated alkyl ions mainly in the lower mass range (C_nH_{2n+1} and C_nH_{2n-1} ; m/z 29, 43, 57, ... and 27, 41, 55, ...). Rearrangement products corresponding to $C_nH_{2n-1}N$ contribute, to a significant extent, to the ion series m/z 41, 55, 69, For alkyl chains with $C_{n>5}$, dominating $(CH_2)_nCN^{+}$ (i.e., $C_nH_{2n-2}N$, m/z 82, 96, 110, ..., probably with a cyclic structure).

Intensities: Intensive peaks due to the above mentioned ions.

Molecular ion: Weak or missing. Both $[M+H]^{+}$ and $[M-H]^{+}$ are usually more intensive than M^{+} . In some aliphatic nitriles, $[M+2H]^{+}$ is as intensive as M^{+} . Odd mass for odd number of N atoms in the molecule.

Aromatic Nitriles ($R-CN$)

N

Fragmentation: Consecutive elimination of HCN and acetylene.

Ion series: Aromatic fragments corresponding to C_nH_n and $C_nH_{n\pm 1}$ (m/z 39, 51–53, 63–65, 75–77, ...).

Intensities: Intensive peaks in the M^{+} region.

Molecular ion: Dominant intensity, often base peak. In contrast to aliphatic and benzylic nitriles, $[M-1]^{+}$ is usually not important. Odd mass for odd number of N atoms in the molecule.

Aliphatic Isonitriles ($R-NC$)

Fragmentation: In general, the spectra are similar to those of the corresponding nitriles. The most important difference lies in the loss of CN^{+} (Δm 26) and the higher probability of losing HCN (Δm 27). Further important fragmentations are the elimination of alkyl radicals to give $(CH_2)_nCN^{+}$ ions and the McLafferty rearrangement to yield $CR_2=N=CH^{+}$ (m/z 41 for R: H).

Ion series: Saturated and unsaturated alkyl ions mainly in the lower mass range (C_nH_{2n+1} , m/z 29, 43, 57, ... and C_nH_{2n-1} , m/z 27, 41, 55, ...). Rearrangement products corresponding to $C_nH_{2n-1}N$ contribute, to a significant extent, to the ion series of m/z 41, 55, 69,

Intensities: Intensive peaks in the lower mass range.

Molecular ion: Weak, decreasing with increasing chain length and degree of branching. Both $[M+H]^+$ and $[M-H]^+$ can be stronger than M^+ . Odd mass for odd number of N atoms in the molecule.

Aromatic Isonitriles ($R-NC$) [4]

Fragmentation: Dominant loss of HCN ($[M-27]^{+}$). In methylphenyl and benzyl isocyanides also formation of isocyanotropylium ion, $[M-1]^+$, followed by loss of HCN to $[M-28]^{+}$.

Ion series: Aromatic (C_nH_n and $C_nH_{n\pm 1}$; m/z 39, 51–53, 63–65, 75–77, ...).

Intensities: Intensive peaks in the higher mass range.

Molecular ion: Dominant; base peak for phenyl isocyanide. Odd mass for odd number of N atoms in the molecule.

8.9.6 Cyanates, Isocyanates, Thiocyanates, and Isothiocyanates

Aliphatic Cyanates ($R-OCN$) [8]

Fragmentation: Spectra often very similar to those of the corresponding isocyanates (see below). Cleavage of the C–C bond next to O, with the charge remaining on CH_2OCN (m/z 56) for short-chain cyanates and preferably on the alkyl substituent if it has a $C_{n>2}$ chain (m/z 29, 43, 57, ...). Cleavage of the C–O bond with H rearrangement to give $HCNO^{+}$ (m/z 43) or alkene $^{+}$ (m/z 42, 56, 70, ...). For cyanates with $C_{n>5}$ substituents, alkene elimination yields m/z 99.

Ion series: Saturated and unsaturated alkyl cations (C_nH_{2n+1} , m/z 29, 43, 57, ... and C_nH_{2n-1} , m/z 27, 41, 55, ...). Alkene radical cations (C_nH_{2n} , m/z 42, 56, 70, ...) together with isobaric ions of the composition $C_nH_{2n}NCO$.

Intensities: Intensive peaks mainly in the lower mass range.

Molecular ion: Usually weak or absent. $[M-H]^+$ is often more intensive. Odd mass for odd number of N atoms in the molecule.

N

Aromatic Cyanates ($R-OCN$) [8]

Fragmentation: Loss of OCN^- ($\Delta m 42$) or, to a lesser extent, of CO ($\Delta m 28$), with subsequent HCN elimination ($\Delta m 27$).

Ion series: Aromatic fragments corresponding to C_nH_n and $C_nH_{n\pm 1}$ (m/z 39, 51–53, 63–65, 75–77, ...).

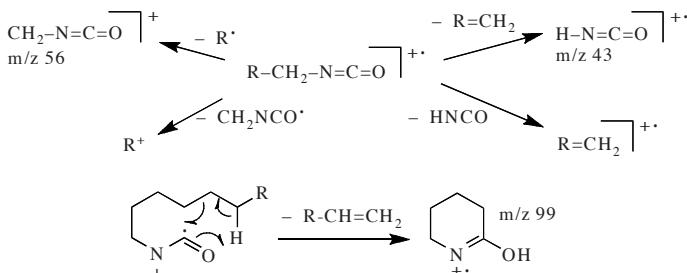

Intensities: Intensive peaks in the higher mass range.

Molecular ion: Strong. Odd mass for odd number of N atoms in the molecule.

Aliphatic Isocyanates ($R-NCO$) [8]

Fragmentation: Spectra often very similar to those of the corresponding cyanates. Cleavage of the C–C bond next to N, the charge remaining on the CH_2NCO (m/z 56) for short-chain isocyanates and preferably on the alkyl substituent for compounds with a $C_{n>2}$ chain (m/z 29, 43, 57, ...). Cleavage of the C–N bond with H

rearrangement to give HNCO^+ (m/z 43) or alkene $^+$ (m/z 42, 56, 70, ...) ions. For isocyanates with $C_{n>5}$ alkyl chains, alkene elimination, yielding m/z 99.

Ion series: Saturated and unsaturated alkyl cations ($C_n\text{H}_{2n+1}$, m/z 29, 43, 57, ...) and $C_n\text{H}_{2n-1}$, m/z 27, 41, 55, ...). Alkene radical cations ($C_n\text{H}_{2n}$, m/z 42, 56, 70, ...) together with isobaric ions of the composition $C_n\text{H}_{2n}\text{OCN}$.

Intensities: Intensive peaks mainly in the lower mass range.

Molecular ion: Usually weak or absent. $[\text{M}-\text{H}]^+$ is often more intensive. Odd mass for odd number of N atoms in the molecule.

Aromatic Isocyanates ($R-\text{NCO}$) [8]

Fragmentation: Consecutive elimination of CO (Δm 28) and HCN (Δm 27). In contrast to aromatic cyanates, practically no elimination of NCO^\cdot (Δm 42).

Ion series: Aromatic fragments corresponding to $C_n\text{H}_n$ and $C_n\text{H}_{n\pm 1}$ (m/z 39, 51–53, 63–65, 75–77, ...).

Intensities: Intensive peaks in the higher mass range.

Molecular ion: Dominating; base peak for phenyl isocyanate. Odd mass for odd number of N atoms in the molecule.

N

Aliphatic Thiocyanates ($R-\text{SCN}$) [8]

Fragmentation: Elimination of HCN (Δm 27) followed by loss of an alkyl group. The cleavage of the C–C bond next to SCN is unimportant except in short-chain thiocyanates.

Ion series: Saturated and unsaturated alkyl cations ($C_n\text{H}_{2n+1}$, m/z 29, 43, 57, ...) and $C_n\text{H}_{2n-1}$, m/z 27, 41, 55, ...).

Intensities: Intensive peaks in the lower mass range.

Molecular ion: Weak. Decreasing with increasing chain length and degree of branching; absent from the spectrum of hexyl thiocyanate. Odd mass for odd number of N atoms in the molecule. Both $[\text{M}+\text{H}]^+$ and $[\text{M}-\text{H}]^+$ are detectable. Characteristic ^{34}S isotope peak at $[\text{M}+2]^{+}$ and $[\text{frag}+2]$ for S-containing fragments (4.5% per S atom).

Aromatic Thiocyanates ($R-\text{SCN}$) [8]

Fragmentation: The most important fragmentation is the elimination of SCN^\cdot (Δm 58). Further elimination reactions are loss of CN^\cdot (Δm 26), HCN (Δm 27),

and CS (Δm 44).

Ion series: Aromatic fragments corresponding to C_nH_n and $C_nH_{n\pm 1}$ (m/z 39, 51–53, 63–65, 75–77, ...). Weak signal at m/z 45 (CHS^+) indicates sulfur.

Intensities: Intensive peaks in the higher mass range.

Molecular ion: Dominant; base peak in phenyl thiocyanate. Odd mass for odd number of N atoms in the molecule. Characteristic ^{34}S isotope peak at $[M+2]^{+}$ and [frag+2] for S-containing fragments (4.5% per S atom).

Aliphatic Isothiocyanates (R-NCS) [8]

Fragmentation: Cleavage of the C–C bond next to NCS, leading to m/z 72 (CH_2NCS) or to its homologues if the α -C atom is substituted. Loss of the alkyl residue with concomitant double hydrogen rearrangement to yield H_2NCS^+ (m/z 60). With a $C_{n>4}$ alkyl chain, loss of SH^- (Δm 33). With $C_{n>5}$ alkyl chains, loss of alkene leading to m/z 115, probably according to the mechanism shown for aliphatic isocyanates.

Ion series: Mainly saturated and unsaturated alkyl cations (C_nH_{2n+1} , m/z 29, 43, 57, ... and C_nH_{2n-1} , m/z 27, 41, 55, ...). Signal for CH_2NCS^+ (m/z 72) or its homologues (m/z 86, 100, 114, ...) if the α -C atom is substituted.

Intensities: Intensive peaks mainly in the lower mass range.

Molecular ion: Medium to weak, decreasing with increasing chain length and degree of branching. More intensive than in the corresponding thiocyanates; 1% for hexadecyl isothiocyanate. Both $[M+H]^+$ and $[M-H]^+$ are relevant. Odd mass for odd number of N atoms in the molecule. Characteristic ^{34}S isotope peak at $[M+2]^{+}$ and [frag+2] for S-containing fragments (4.5% per S atom).

Aromatic Isothiocyanates (Ar-NCS) [8]

Fragmentation: Dominant loss of NCS^- (Δm 58). In contrast to aromatic thiocyanates, the loss of HCN (Δm 27) or CS (Δm 44) leads to very weak fragments only.

Ion series: Aromatic fragments corresponding to C_nH_n and $C_nH_{n\pm 1}$ (m/z 39, 51–53, 63–65, 75–77, ...). Weak signal at m/z 45 (CHS^+) indicates sulfur.

Intensities: Intensive peaks in the higher mass range.

Molecular ion: Dominant; base peak in phenyl isothiocyanate. Odd mass for odd number of N atoms in the molecule. Characteristic ^{34}S isotope peak at $[M+2]^{+}$ and [frag+2] for S-containing fragments (4.5% per S atom).

8.10 Sulfur Compounds [1]

8.10.1 Thiols

Aliphatic Thiols [2]

Fragmentation: Elimination of H_2S (Δm 34; or SH , Δm 33, from secondary thiols) followed by loss of alkenes; consecutive losses of ethylene from unbranched thiols. Cleavage of the α,β -C–C bond (next to the SH group) leads to CH_2SH^+ (m/z 47). Note that this fragment also occurs in secondary and tertiary thiols. The S atom is poorer than N, but better than O, at stabilizing such a fragment. Cleavage at the next C–C bonds leads to signals at m/z 61, 75, and 89. In secondary and tertiary thiols, prominent fragments are formed by loss of the largest α -alkyl group.

Ion series: Dominant alkenyl fragments ($\text{C}_n\text{H}_{2n-1}$, m/z 41, 55, 69, ...) and smaller aliphatic fragments ($\text{C}_n\text{H}_{2n+1}$, m/z 43, 57, 71, ...). Sulfur-containing aliphatic fragments: $\text{C}_n\text{H}_{2n+1}\text{S}$ (m/z 47, 61, 75, 89, ...). Often significant sulfur-indicating fragments: HS^+ , H_2S^+ , H_3S^+ , and CHS^+ (m/z 33, 34, 35, and 45).

Intensities: More intensive peaks in the lower mass range, mostly of the alkene type. Characteristic local maxima from S-containing fragments, $\text{C}_n\text{H}_{2n+1}\text{S}$ (m/z 47, 61, 75, 89, ...). In n -alkyl thiols, the intensity of the signal at m/z 61 is roughly half that of m/z 47; the signal at m/z 89 is more intensive than that at m/z 75, presumably because it is stabilized by cyclization.

Molecular ion: Relatively strong except for higher tertiary thiols. Characteristic ^{34}S isotope peak at $[\text{M}+2]^{+}$ and $[\text{frag}+2]$ for S-containing fragments (4.5% per S atom).

Aromatic Thiols [2]

Fragmentation: CS elimination from M^+ and $[\text{M}-1]^+$, yielding $[\text{M}-44]^{+}$ and $[\text{M}-45]^{+}$. HS^- elimination from M^+ to give $[\text{M}-33]^{+}$.

Ion series: HCS^+ (m/z 45) is characteristic besides the aromatic fragments, C_nH_n and $\text{C}_n\text{H}_{n\pm 1}$ (m/z 39, 51–53, 63–65, 75–77, ...).

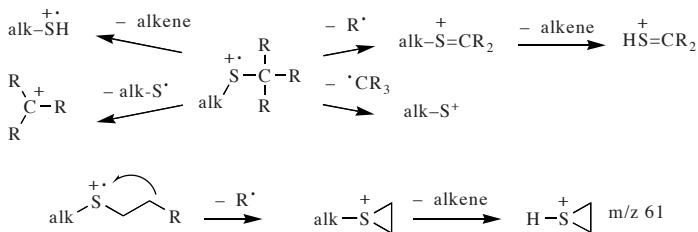

Intensities: Intensive peaks in the higher mass range.

Molecular ion: Usually dominating; base peak in thiophenol. $[\text{M}-1]^+$ is usually strong. Characteristic ^{34}S isotope peak at $[\text{M}+2]^{+}$ and $[\text{frag}+2]$ for S-containing fragments (4.5% per S atom).

8.10.2 Sulfides and Disulfides

Aliphatic Sulfides [1]

Fragmentation: Loss of alkyl radicals by cleavage of the C–C bond next to S (the largest group being lost preferably) and of the C–S bond, followed by alkene and H_2S elimination. Alkene elimination from M^+ to form the corresponding thiol ions. In contrast to thiols and cyclic sulfides, no H_2S or HS^- elimination from M^+ .

In general, the H rearrangements are nonspecific. The transfer of secondary H predominates over that of primary H.

Ion series: Sulfur-containing aliphatic fragments, $\text{C}_n\text{H}_{2n+1}\text{S}$ (m/z 47, 61, 75, 89, ...). The hydrocarbon fragments may dominate in long-chain sulfides.

Intensities: Intensive peaks in the lower mass range. Characteristic local maxima from S-containing fragments, $\text{C}_n\text{H}_{2n+1}\text{S}$ (m/z 47, 61, 75, 89, ...).

Molecular ion: Usually strong. Characteristic ^{34}S isotope peak at $[\text{M}+2]^+$ and $[\text{frag}+2]$ for S-containing fragments (4.5% per S atom).

Alkyl Vinyl Sulfides

Fragmentation: Loss of alkyl radicals (Δm 15, 29, 43, ...). Elimination of thioethanol (Δm 62) after triple H rearrangement. Dominant m/z 60 ($\text{CH}_3\text{CH=S}^+$) accompanied by m/z 61 ($\text{CH}_3\text{CH}_2\text{S}^+$).

Ion series: Sulfur-containing unsaturated aliphatic fragments, $\text{C}_n\text{H}_{2n-1}\text{S}$ (m/z 45, 59, 73, ...). Unsaturated hydrocarbon ions, C_nH_{2n} (m/z 42, 56, 70, ...) and $\text{C}_n\text{H}_{2n-2}$ (m/z 40, 54, 68, ...)

Intensities: Intensive peaks evenly distributed over the whole mass range.

Molecular ion: Of medium intensity. Characteristic ^{34}S isotope peak at $[\text{M}+2]^+$ and $[\text{frag}+2]$ for S-containing fragments (4.5% per S atom).

Cyclic Sulfides

S

Fragmentation: Primary cleavage of the C–C bond next to S, followed by rearrangements and elimination of $\text{CH}_3\cdot$ (base peak for tetrahydrothiopyrane) and $\text{C}_2\text{H}_5\cdot$. In tetrahydrothiophene, $[\text{M}-1]^+$ is also significant. $\text{HS}\cdot$, H_2S , and C_2H_4 elimination from M^+ .

Ion series: Sulfur-containing aliphatic fragments with one degree of unsaturation, $\text{C}_n\text{H}_{2n-1}\text{S}$ (m/z 45, 59, 73, 87, 101, ...), m/z 87 being of special dominance.

Intensities: Overall distribution of peaks maximizing in the low mass range due to S-containing fragments, $\text{C}_n\text{H}_{2n-1}\text{S}$ (m/z 45, 59, 73, 87, ...).

Molecular ion: Very strong. Characteristic ^{34}S isotope peak at $[\text{M}+2]^+$ and $[\text{frag}+2]$ for S-containing fragments (4.5% per S atom).

Aromatic Sulfides [2]

Fragmentation: Loss of CS (Δm 44) and of $\text{HS}\cdot$ (Δm 33) from M^+ .

Ion series: HCS^+ (m/z 45) is characteristic besides the aromatic fragments, C_nH_n and $\text{C}_n\text{H}_{n\pm 1}$ (m/z 39, 51–53, 63–65, 75–77, ...).

Intensities: Intensive peaks mainly in the higher mass range.

Molecular ion: Strong. Characteristic ^{34}S isotope peak at $[\text{M}+2]^{+}$ (4.5% relative to M^{+} per S atom) and $[\text{frag}+2]$ for S-containing fragments.

Disulfides

Fragmentation: Loss of RSS^{\cdot} , leading to alkyl cations and alkene elimination to give RSSH^{+} . Cleavage of the S–S bond with or without H rearrangements, leading to RS^{+} , $[\text{RS}-\text{H}]^{+}$, and $[\text{RS}-2\text{H}]^{+}$. Loss of one or two S with or without H atoms is a common process in cyclic, unsaturated, and aromatic disulfides.

Ion series: In saturated aliphatic disulfides, H_2S_2 and its alkyl homologues are characteristic (m/z 66, 80, 94, ...).

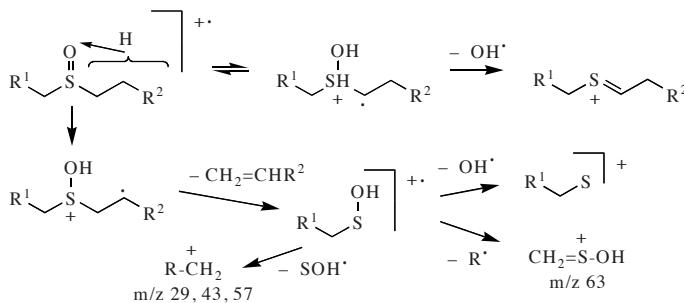

Intensities: Variable.

Molecular ion: Usually strong. Characteristic ^{34}S isotope peak at $[\text{M}+2]^{+}$ and $[\text{frag}+2]$ for S-containing fragments (4.5% per S atom).

8.10.3 Sulfoxides and Sulfones

Aliphatic Sulfoxides [4,5]

Fragmentation: Most fragments are produced after rearrangement with non-specific H transfer to the O atom and subsequent OH $^{\cdot}$ elimination to yield $[\text{M}-17]^{+}$ or alkene elimination to $[\text{M-alkene}]^{+}$, followed by OH $^{\cdot}$, SOH $^{\cdot}$ (giving alk $^{+}$ ions), or alk $^{\cdot}$ elimination (yielding $\text{CH}_2=\text{S-OH}^{+}$, m/z 63).

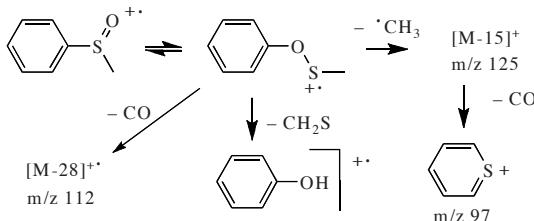

Ion series: Characteristic ion at m/z 63 ($\text{CH}_2=\text{S-OH}^{+}$) as well as alkyl and alkenyl fragments, $\text{C}_n\text{H}_{2n+1}$ (29, 43, 57, 71, ...) and $\text{C}_n\text{H}_{2n-1}$ (27, 41, 55, 69, ...).

Intensities: Intensive peaks evenly distributed over the whole mass range.

Molecular ion: Of medium intensity. Characteristic ^{34}S isotope peak at $[\text{M}+2]^{+}$ and $[\text{frag}+2]$ for S-containing fragments (4.5% per S atom).

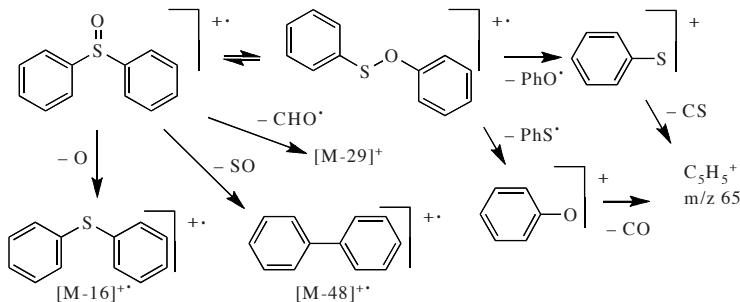

Alkyl Aryl and Diaryl Sulfoxides [4,5]

Fragmentation: Most fragments of methyl aryl sulfoxides are produced, after rearrangement to $\text{CH}_3\text{S}-\text{O}-\text{ar}^+$, by elimination of CH_2S (yielding $[\text{M}-46]^+$, a phenol), of CO (to $[\text{M}-28]^+$), and of CH_3^+ (to $[\text{M}-15]^+$). The latter ion loses CO to give the thiapyranyl cation (m/z 97 if ar is phenyl).

The skeletal rearrangement is not relevant for the fragmentation of higher alkyl aryl sulfoxides. Here, direct cleavage of the C–S bonds and McLafferty rearrangements dominate.

For diaryl sulfoxides, elimination of SO (to give $[\text{M}-48]^+$) as well as of O, OH^+ , and CHO^+ (yielding $[\text{M}-16]^+$, $[\text{M}-17]^+$, and $[\text{M}-29]^+$, respectively). After rearrangement to sulfenates, cleavage of the S–O bond to produce ar-S^+ and ar-O^+ ions, which further lose CS and CO, respectively, to give C_5H_5^+ (m/z 65).

S

Ion series: Besides the ions described under *Fragmentation*, mainly fragments of the aromatic type, i.e., C_nH_n and $\text{C}_n\text{H}_{n\pm 1}$ (m/z 39, 51–53, 63–65, 75–77, ...), as well as O- and S-containing ions.

Intensities: Intensive peaks mainly in the high mass range.

Molecular ion: Very strong. Characteristic ^{34}S isotope peak at $[\text{M}+2]^+$ and $[\text{frag}+2]$ for S-containing fragments (4.5% per S atom).

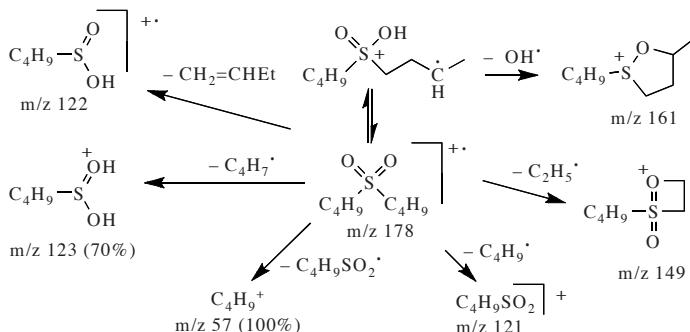

Aliphatic Sulfones [4,5]

Fragmentation: Fragmentation of the S–C bond with the charge remaining on either side. Single and double H rearrangements to give RS(O)OH^+ and RS(OH)_2^+ . The probability of the double H rearrangement increases with increasing chain length. If one of the substituents is unsaturated, rearrangement to RS(O)O-alkene followed by cleavage of the S–O bond yields the ion RSO^+ .

Ion series: Dominating aliphatic fragments, C_nH_{2n+1} (m/z 29, 43, 57, ...) and C_nH_{2n-1} (m/z 27, 41, 55, ...). Usually, one significant fragment corresponding to alk-S(O)OH $^+$ (from the series of m/z 80, 94, 108, ...) or alk-S(OH) $_2^+$ (from the series of m/z 81, 95, 109, ...) can be observed.

Intensities: Intensive peaks mainly of aliphatic fragments in the lower mass range.

Molecular ion: Weak. Characteristic ^{34}S isotope peak at [M+2] $^+$ and [frag+2] for S-containing fragments (4.5% per S atom).

Cyclic Sulfones [4]

Fragmentation: Dominant elimination of SO_2 ($\Delta m 64$, followed by loss of $CH_3\cdot$), $HSO_2\cdot$ ($\Delta m 65$, followed by loss of C_2H_4), or CH_2SO_2 ($\Delta m 78$). Weak signal at [M-17] $^+$ due to $OH\cdot$ elimination.

Ion series: Mainly unsaturated hydrocarbon fragments, C_nH_{2n-1} (m/z 27, 41, 55, ...).

Intensities: Intensive peaks in the lower mass range.

Molecular ion: Moderate. Characteristic ^{34}S isotope peak at [M+2] $^+$ and [frag+2] for S-containing fragments (4.5% per S atom).

Alkyl Aryl Sulfones [4]

S

Fragmentation: Isomerization of M^+ to ar-OS(=O)alk and formation of the phenoxy ion or the phenol radical cation with H rearrangement. The migration of the aryl group depends on the type of substituents. It is facilitated by electron donors and hindered by acceptors. Mainly in substituted or unsaturated alkyl derivatives also isomerization to ar-S(=O)O-alk(ene) and formation of ar-S=O $^+$ (m/z 125 if ar is phenyl). Single and double H rearrangements to give ar-S(=O)OH $^+$ and ar-S(OH) $_2^+$. The probability of the double H rearrangement increases with increasing chain length. In some derivatives, SO_2 elimination from M^+ dominates. Substituents X of the alkyl group may migrate to the aryl group to yield X-ar-S=O $^+$ ions.

Ion series: Aromatic hydrocarbon fragments, C_nH_n and $C_nH_{n\pm 1}$ (m/z 39, 51–53, 63–65, 75–77, ...), as well as S- and O-containing aromatic fragments at higher masses.

Intensities: Intensive peaks mainly in the higher mass range.

Molecular ion: Strong. Characteristic ^{34}S isotope peak at [M+2] $^+$ and [frag+2] for S-containing fragments (4.5% per S atom).

Diaryl Sulfones [4,5]

Fragmentation: Predominant aromatic fragments of the type ar-O⁺ and ar-SO⁺ (m/z 125 if ar is phenyl), formed after migration of one of the aryl groups. The ar-SO₂⁺ ion is unimportant; ar⁺ is intensive. Small signals due to SO₂, SO₂H[·], and SO₂H₂ eliminations (Δm 64, 65, and 66, respectively). With alkyl substituents in *ortho* position, [M-OH]⁺ and [M-H₂O]⁺ are formed, upon which SO elimination follows.

Ion series: Aromatic fragments, C_nH_n and C_nH_{n±1} (m/z 39, 51–53, 63–65, 75–77, ...) and the S- and O-containing aromatic fragments at higher masses. Usually, ar-SO⁺ (m/z 125 if ar is phenyl) is very strong.

Intensities: Intensive peaks mainly in the higher mass range.

Molecular ion: Strong. Characteristic ³⁴S isotope peak at [M+2]⁺ and [frag+2] for S-containing fragments (4.5% per S atom).

8.10.4 Sulfonic Acids and Their Esters and Amides

Aromatic Sulfonic Acids [6]

Fragmentation: The most prominent fragment, [M-HSO₃]⁺ (Δm 81), is formed in a two-step process. In the first step, OH[·] elimination leads to a weak fragment ion [M-OH]⁺ (Δm 17). If an alkyl group is present in *ortho* position, [M-H₂SO₃]⁺ (Δm 82) is formed instead of [M-81]⁺. Other important fragments are [M-SO₂]⁺ (Δm 64), [M-HSO₂]⁺ (Δm 65), and [M-SO₃]⁺ (Δm 80).

Ion series: Aromatic hydrocarbon fragments, C_nH_n and C_nH_{n±1} (m/z 39, 51–53, 63–65, 75–77, ...), and O-containing aromatic fragments at higher masses.

Intensities: Intensive peaks mainly in the higher mass range.

Molecular ion: Very strong. Characteristic ³⁴S isotope peak at [M+2]⁺ and [frag+2] for S-containing fragments (4.5% per S atom).

S

Alkylsulfonic Acid Esters [6]

Fragmentation: Loss of alkyl by fragmentation of the C–O bond with concomitant double H rearrangement to form the protonated sulfonic acid ion (m/z 97 for methanesulfonates), which then loses water. Loss of the alkoxy residue (fragmentation of the S–O bond). Formation of an alkene ion from the alkyl ester group by a McLafferty-type rearrangement. In aryl esters, the phenoxy ion and the phenol radical cations dominate the spectrum.

Ion series: Besides RSO₃H₂⁺ and RSO₂⁺ (m/z 97 and 79 for methanesulfonates), for aliphatic esters mainly alkene fragments. In aryl esters, aromatic fragments, C_nH_n and C_nH_{n±1} (m/z 39, 51–53, 63–65, 75–77, ...), as well as O-containing aromatic fragments at higher masses.

Intensities: Intensive peaks in the lower mass range.

Molecular ion: Small or negligible signal for alkyl esters; intensive for aryl esters. Characteristic ³⁴S isotope peak at [M+2]⁺ and [frag+2] for S-containing fragments (4.5% per S atom).

Arylsulfonic Acid Esters [6]

Fragmentation: Dominating fragments resulting from cleavage of the S–O bond (leading to the ar–SO₂⁺ ion), which loses SO₂ (m/z 155 and 91 for *p*-toluenesulfonates). In arylsulfonates with longer chains, double H rearrangement to give the protonated acid (m/z 173 for *p*-toluenesulfonates).

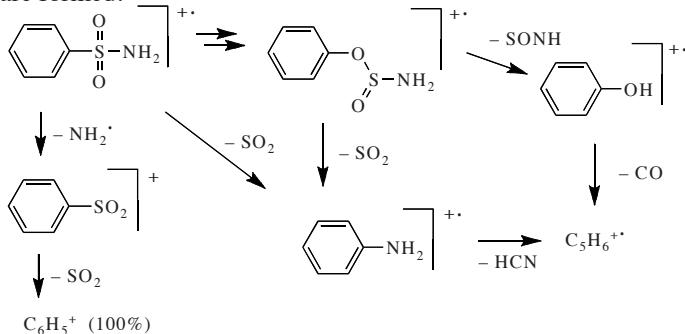

Ion series: Aromatic hydrocarbon fragments, C_nH_n and C_nH_{n±1} (m/z 39, 51–53, 63–65, 75–77, ...).

Intensities: Intensive peaks mainly in the higher mass range.

Molecular ion: Medium or weak. Characteristic ³⁴S isotope peak at [M+2]⁺ and [frag+2] for S-containing fragments (4.5% per S atom).

Aromatic Sulfonamides [6]

Fragmentation: In *N*-alkylamides, the C–C bond next to N is split preferably. In *N*-arylsulfonamides, besides [M–SO₂]⁺ and [M–HSO₂]⁺, the ions ar–SO₂⁺ and ar'–NH⁺ are formed.

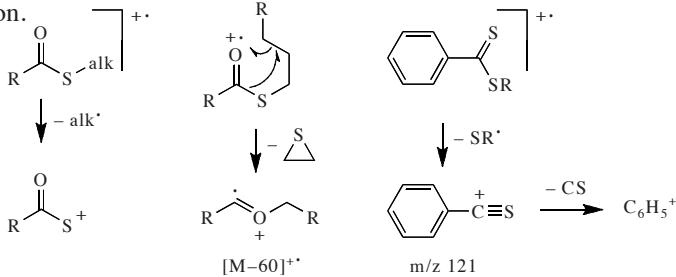

Ion series: Typical for the tosyl group are ions at m/z 155, 91, and 65.

Molecular ion: In arylsulfonamides, M⁺ is dominant. Characteristic ³⁴S isotope peak at [M+2]⁺ and [frag+2] for S-containing fragments (4.5% per S atom).

S

8.10.5 Thiocarboxylic Acid Esters [7]

In contrast to esters, the major fragmentation process is elimination of the alkyl radical from the thiol site. Ethylene sulfide is eliminated from thioesters with longer alkyl chains. Aromatic dithiocarboxylic acid esters usually fragment in two steps to the aryl cation.

8.11 Carbonyl Compounds [1–4]

8.11.1 Aldehydes

Aliphatic Aldehydes [5]

Fragmentation: Cleavage of the bond next to CO. The fragmentation of the hydrocarbon chain is similar to that in corresponding alkanes. McLafferty rearrangement with localization of the charge on either side, giving rise to $C_nH_{2n}^{+}$ (m/z 28, 42, 56, ...) and, often less important, to $C_nH_{2n}O^{+}$ ions (m/z 44, 58, 72, ...). At least one product (often both) is significant. Elimination of water from the molecular ion to give $[M-18]^{+}$, occasionally very pronounced.

Ion series: Dominating fragments of the series of C_nH_{2n+1} and $C_nH_{2n-1}O$ (in both cases: m/z 29, 43, 57, ...). Weaker signals of the series C_nH_{2n-1} (m/z 41, 55, 69, ...) and rearrangement products, C_nH_{2n} (m/z 28, 42, 56, ...).

Intensities: Intensive peaks concentrated in the lower mass range. Local even-mass maxima from McLafferty-type reactions ($[M-44]^{+}$ when the aldehyde is not substituted in α -position).

Molecular ion: Only strong for molecules of low molecular weight; very weak for $C_{n>9}$. $[M-1]^{+}$ may be more relevant than M^{+} .

Unsaturated Aliphatic Aldehydes

Fragmentation: Cleavage of the bond next to CO, leading to $[M-1]^{+}$ (more significant than in saturated aldehydes), $[M-29]^{+}$, and m/z 29. No McLafferty rearrangement occurs if the γ -hydrogen atom is attached to a double-bonded carbon or if there is a double bond in α,β -position.

Ion series: Fragments of the series of C_nH_{2n-1} and $C_nH_{2n-3}O$ (in both cases, m/z 41, 55, 69, ...).

Molecular ion: Stronger than in saturated aldehydes. Usually, $[M-1]^{+}$ is relevant.

Aromatic Aldehydes

Fragmentation: Characteristic H[·] loss to yield the corresponding benzoyl ion, $[M-1]^{+}$, followed by decarbonylation to a phenyl ion, $[M-1-28]^{+}$, of lower intensity. To a small extent also decarbonylation of the molecular ion, leading to $[M-28]^{+}$. Weak signal at m/z 29 (CHO^{+}).

C = X

Ion series: Aromatic fragments corresponding to C_nH_n and $C_nH_{n\pm 1}$ (m/z 39, 51–53, 63–65, 75–77, ...).

Intensities: Intensive peaks predominantly in the molecular ion region.

Molecular ion: Usually prominent. $[M-1]^{+}$ is strong.

8.11.2 Ketones

Aliphatic Ketones

Fragmentation: Cleavage of the bond next to CO is the most important primary fragmentation. The charge can remain on either side. The acyl ions then lose CO. McLafferty rearrangement giving rise to $C_nH_{2n}O^+$ ions (m/z 58, 72, 86, ...). Consecutive rearrangements occur if both alkyl chains contain a γ -H atom. Keto-enol tautomerism of the first rearrangement product is not a prerequisite for the second rearrangement to occur. Oxygen is sometimes indicated by weak signals at $[M-18]^+$ and m/z 31, 45, 59. Fragmentation of the hydrocarbon chain similar to that in the corresponding alkanes.

Ion series: Dominating fragments of the series C_nH_{2n+1} and $C_nH_{2n-1}O$ (in both cases m/z 29, 43, 57, ...), but often distinguishable by the intensity of the ^{13}C isotope signal), with maxima due to cleavage at the CO group to give acyl ions and their decarbonylation products. Weaker signals in the series C_nH_{2n-1} (m/z 41, 55, 69, ...). Even-mass maxima, $C_nH_{2n}O$ (m/z 58, 72, 86, ...), due to alkene elimination (McLafferty rearrangement). Usually, m/z 43 (CH_3CO^+) is strong if an unsubstituted α - CH_2 group is present.

Intensities: Intensive peaks mainly in the lower mass range.

Molecular ion: Relatively abundant, weak in long-chain and branched ketones.

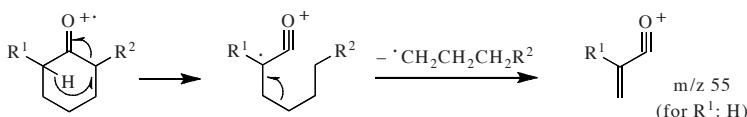

Unsaturated Ketones

Fragmentation: Cleavage of the bond next to CO, more favorably on the saturated side, is the most important primary fragmentation. The acyl ion then loses CO. The McLafferty rearrangement occurs neither when the unsaturated substituents are in α,β -position nor when the only available γ -hydrogen atom is attached to a double-bonded carbon.

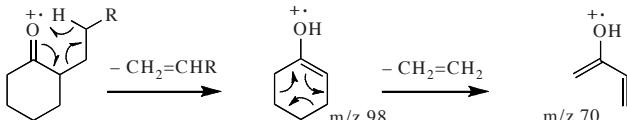

Molecular ion: Relatively abundant.

Cyclic Ketones

Fragmentation: Major primary fragmentation by bond cleavage next to carbonyl, followed by loss of alkyl residue.

Prominent McLafferty-type elimination of larger alkyl groups in position 2 or 6 as alkenes. This rearrangement is very favorable; even aromatically bonded H atoms can rearrange. For cyclohexanones, a consecutive retro-Diels–Alder reaction can occur:

Oxygen is sometimes indicated by a weak signal at $[M-18]^+$.

Ion series: Alkene fragments of the type of C_nH_{2n-1} or $C_nH_{2n-3}O$ (for both: m/z 41, 55, 69, ...) with maxima due to alkyl loss after ring opening next to the carbonyl group and H transfer. Prominent even-mass maxima by elimination of substituents at position 2 or 6 as alkenes via sterically favored McLafferty rearrangements.

Intensities: Overall more intensive peaks in the lower mass range or even distribution of major peaks over the whole mass range. Local maxima from major fragmentation pathway.

Molecular ion: Abundant.

Aromatic Ketones

Fragmentation: Dominant α -cleavage to give the benzoyl ion, followed by decarbonylation to a phenyl ion of lower intensity. α -Cleavage in acetophenone also produces the acetyl cation (m/z 43). Even-mass maxima due to alkene elimination via McLafferty rearrangement. CO elimination from diaryl ketones through skeletal rearrangements.

Ion series: Aromatic fragments corresponding to C_nH_n and $C_nH_{n\pm 1}$ (m/z 39, 51–53, 63–65, 75–77, ...).

Intensities: Intensive peaks predominantly in the molecular ion region.

Molecular ion: Strong.

8.11.3 Carboxylic Acids

Aliphatic Carboxylic Acids

Fragmentation: Cleavage of the C–CO bond leading to m/z 45 and to $[M-45]^+$. Loss of OH[·] leading to $[M-17]^+$; may be followed by decarbonylation. Cleavage of the γ -bond (relative to CO) leads to $^+CH_2CH_2COOH$ (m/z 73) if there is no branching on the α - and β -C atoms. Loss of H[·] (not the carboxylic one) gives $[M-1]^+$. Water elimination to give $[M-18]^+$ if the alkyl group consists of at least 4 C atoms; may be followed by decarbonylation. McLafferty rearrangement to m/z 60 (acetic acid) if there is no α -substituent.

Ion series: Saturated and unsaturated alkyl ions mainly in the lower mass range (C_nH_{2n+1} and C_nH_{2n-1} , m/z 29, 43, 57, ... and 27, 41, 55, ...). With long-chain aliphatic acids, $C_nH_{2n-1}O_2$ series (m/z 59, 73, 87, ...), exhibiting maxima for n = 3, 7, 11, 15, ... (m/z 73, 129, 185, 241, ...). Even-mass maxima, $C_nH_{2n}O_2$ (m/z 60, 74, 88, ...), due to McLafferty rearrangements.

C = X

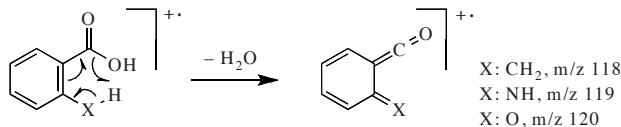

Intensities: Intensive peaks due to the above mentioned ions.

Molecular ion: Generally detectable. Easily protonated to $[M+H]^+$.

Aromatic Carboxylic Acids

Fragmentation: Pronounced loss of OH[·], leading to $[M-17]^+$ and followed by decarbonylation (Δm 28) to a phenyl ion of lower intensity. Water elimination to

$[M-18]^{+*}$ if a H-bearing *ortho*-substituent is present. Some acids decarboxylate ($\Delta m 44$). Loss of CO ($\Delta m 28$) from M^{+*} .

Ion series: Aromatic hydrocarbon fragments, C_nH_n and $\text{C}_n\text{H}_{n\pm 1}$ (m/z 39, 51–53, 63–65, 75–77, ...).

Intensities: Intensive peaks predominantly in the molecular ion region.

Molecular ion: Strong.

8.11.4 Carboxylic Acid Anhydrides

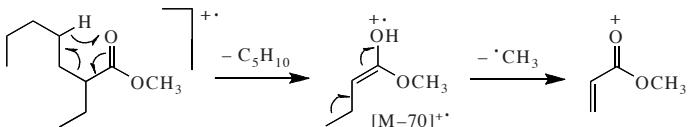

Fragmentation: In the case of linear anhydrides, abundant acyl ions due to cleavage next to carbonyl group. For cyclic anhydrides, maxima due to decarboxylation ($\Delta m 44$), followed by decarbonylation.

Molecular ion: Weak or absent (especially in linear aliphatic anhydrides), easily protonated to $[\text{M}+\text{H}]^{+}$. Relatively strong for phthalic anhydrides.

8.11.5 Esters and Lactones

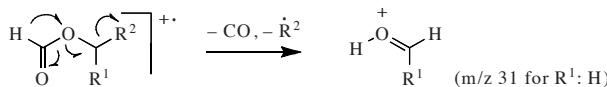

Esters of Aliphatic Carboxylic Acids

Fragmentation: Dominant fragmentation of the bonds next to the carbonyl C, leading to alk-CO^{+} (m/z 43, 57, 71, ...; decreasing intensity with increasing length of the alkyl chain) and followed by decarbonylation, as well as fragmentation to COOR^{+} (m/z 59, 73, 87, ...) and to alk^{+} (m/z 15, 29, 43, ...). Alcohol elimination to give $\text{C}_n\text{H}_{2n-2}\text{O}$ (m/z 42, 56, 70, ...), followed by decarbonylation ($\Delta m 28$) or ketene elimination ($\Delta m 42$). Alkene elimination from the acid side via McLafferty rearrangements, leading to $\text{C}_n\text{H}_{2n}\text{O}_2$ (m/z 60, 74, 88, ...). The larger alkyl group participates in the rearrangement if several γ -H atoms are available. In the following example, the alternative process leading to $[\text{M}-\text{C}_2\text{H}_4]^{+*}$ is negligible:

Nonspecific H rearrangements on the alcohol side (from M^{+*} or the McLafferty product) lead to $\text{C}_n\text{H}_{2n}\text{O}_2$ and to the corresponding alkene, C_nH_{2n} (m/z 28, 42, 56, ...). In methyl esters of long chain acids, the ions $[(\text{CH}_2)_{2+4n}\text{COOCH}_3]^{+}$ (m/z 87, 143, 199, ...) correspond to maxima. For esters of higher alcohols ($\text{C}_{n\geq 3}$), double H rearrangement to the protonated acid, $\text{C}_n\text{H}_{2n+1}\text{CO}_2\text{H}_2^{+}$ (m/z 61, 75, 89, ...). α -Substituted esters may lose the substituent and then CO ($\Delta m 28$) via alkoxy rearrangement. Analogously, β -substituted esters may eliminate ketene ($\Delta m 42$).

Besides usual ester reactions, specific rearrangements can be observed in formates.

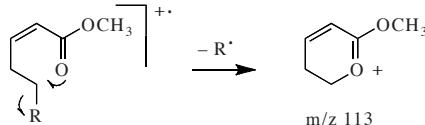

Ion series: C_nH_{2n+1} (m/z 29, 43, 57, ...) for the alkyl groups at the ester oxygen (except for methyl esters). C_nH_{2n-1} (m/z 27, 41, 55, ...). $C_nH_{2n-1}O_2$ (m/z 59, 73, 87, ...), exhibiting maxima for $n = 4, 8, 12, \dots$ (m/z 87, 143, 199, ...) in the case of methyl esters of long-chain acids. Even-mass maxima for $C_nH_{2n}O_2$ (m/z 60, 74, 88, ...) due to alkene elimination via McLafferty rearrangements on both sides of the carboxyl group. C_nH_{2n} (m/z 28, 42, 56, ...) as H rearrangement product from the alcohol side.

Intensities: Intensive peaks due to the above mentioned ions in the lower mass range.

Molecular ion: Often of low abundance. Easily protonated to $[M+H]^+$.

Esters of Unsaturated Carboxylic Acids

α,β -*Unsaturated esters:* Loss of alk-O· followed by CO elimination is the dominant fragmentation path. Also, loss of the δ -substituent yields a 6-membered oxonium ring:

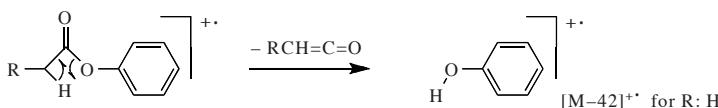

Significant difference between *Z* and *E* isomers of long-chain α,β -unsaturated esters: Single H rearrangement occurs with *Z* esters, and double H rearrangements (leading to protonated acids) have been found for *E* esters.

β,γ -*Unsaturated esters:* Only slight qualitative, but significant quantitative differences have been observed as compared to α,β -unsaturated esters (e.g., less intensive signals for M^+ of β,γ - than of α,β -unsaturated esters).

γ,δ -*Unsaturated esters:* Loss of the alcohol chain as a radical, $R\cdot$, followed by ketene elimination.

Aliphatic enol esters and aryl esters: Formation of alk-CO $^+$ (m/z 43, 57, 71, ...). Elimination of a ketene to give the enol or phenol radical cation. The rearrangement occurs predominantly, but not exclusively, through a 4-membered transition state:

C = X

Esters of Aromatic Acids

Fragmentation: Dominant loss of RO· to form the benzoyl ion, followed by decarbonylation ($\Delta m 28$) and further loss of acetylene ($\Delta m 26$). Ethyl esters also eliminate C_2H_4 ($\Delta m 28$) to give the acid radical cation, which then loses OH· to yield the benzoyl ion. In higher alkyl esters, besides the acid, the protonated

acid is formed (double H rearrangement). In *ortho*-substituted aryl esters with an α -hydrogen atom on the substituent, an alcohol is eliminated from M^+ . In the case of alkyl phthalates (other than dimethyl phthalate), alkenyl elimination from one ester group to give the protonated ester acid, followed by alkene elimination from the other ester group, and subsequent water elimination to the protonated anhydride ion, which forms the base peak at m/z 149.

Ion series: Aromatic hydrocarbon fragments, C_nH_n and $C_nH_{n\pm 1}$ (m/z 39, 51–53, 63–65, 75–77, ...).

Intensities: Prominent maximum at the mass of the related benzoyl ion and its decarbonylation product.

Molecular ion: Usually strong.

Lactones

Fragmentation: The most prominent reaction is the loss of substituents (or H^\cdot) at the O-bearing C atom, followed by decarbonylation (Δm 28), decarboxylation (Δm 44, mainly in smaller molecules), and ketene elimination (Δm 42). Decarboxylation of M^+ is rarely significant. Competing reactions are several kinds of primary ring cleavages. Aromatic lactones show maxima due to two consecutive decarbonylations.

Ion series: No specific ion series. The acetyl ion (m/z 43) is often an important fragment.

Intensities: Maxima at the mass resulting from loss of substituents at the C atom next to oxygen. Otherwise, intensive peaks evenly distributed over the whole mass range.

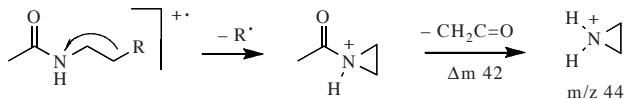

Molecular ion: Usually of low intensity and easily protonated to $[M+H]^+$ in aliphatic lactones; abundant in the case of aromatic lactones.

8.11.6 Amides and Lactams

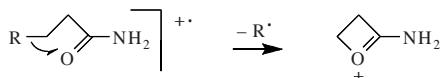

Amides of Aliphatic Carboxylic Acids

C=X

Fragmentation: Alkene elimination on the acid side via McLafferty reaction to yield the corresponding acetamide radical cation. Loss of alkenes on the amine side to give the ion of the desalkyl amide, often via double H rearrangement to the protonated desalkyl amide ion. Bond cleavage on both sides of the carbonyl group. Cleavage of the C–C bond attached to N, and the β,γ -C–C bond (relative to N):

Cleavage of the bonds to the β -C (see scheme) and to the γ -C on the acid side.

Ion series: Even-mass fragments corresponding to $C_nH_{2n}NO$ (m/z 44, 58, 72, ...)

produced by cleavage of the bond next to CO on the acid side. Odd-mass fragments (in secondary and tertiary amides), $C_nH_{2n-1}O$ (m/z 43, 57, 71, ...), produced by cleavage of the bond next to CO on the amine side.

Intensities: Overall peak distribution maximizing in the low mass range. Local maxima from McLafferty and from γ -cleavage products.

Molecular ion: Significant. Strong tendency to protonate to $[M+H]^+$.

Amides of Aromatic Carboxylic Acids

Fragmentation: Maxima due to amide bond cleavage yielding the benzoyl ion, followed by decarbonylation (Δm 28).

Ion series: Aromatic fragments corresponding to C_nH_n and $C_nH_{n\pm 1}$ (m/z 39, 51–53, 63–65, 75–77, ...).

Intensities: Intensive peaks predominantly in the molecular ion region.

Molecular ion: Abundant. $[M-H]^+$ is significant in *N,N*-disubstituted anilides, weaker in monosubstituted derivatives, and absent from the spectrum of benzamide. It is formed exclusively by loss of *ortho*-hydrogens of the aromatic ring.

Anilides

Formanilides: Loss of CO (Δm 28) to give the aniline radical cation and consecutive HCN elimination (Δm 27).

Acetanilides: Ketene elimination gives the aniline radical cation (often base peak), which can eliminate HCN (Δm 27), and formation of the acetyl cation (m/z 43).

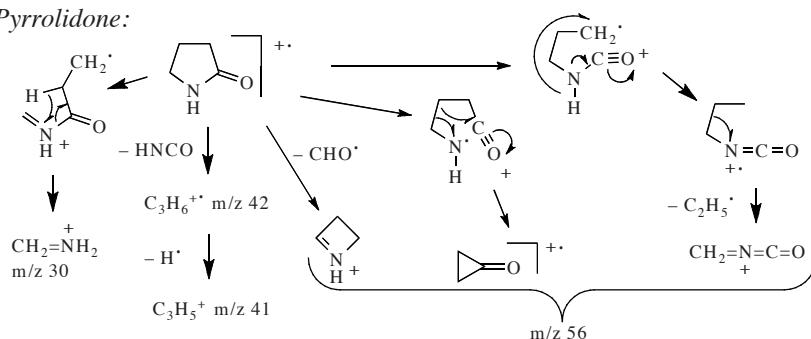

Trichloroacetanilides: Dominant loss of CCl_3^{\cdot} (Δm 117).

Pivalanilides: Besides reactions analogous to those of acetanilides (Δm 84, formation of the aniline radical cation), also formation of the *tert*-butylbenzene radical cation through elimination of HNCO (Δm 43).

Lactams

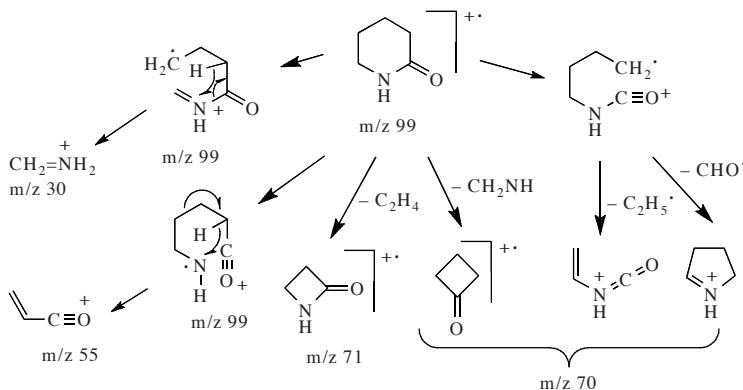

Fragmentation: Cleavage of the C–C bond at the N-bearing C atom. Cleavage of the CO–N bond, followed by loss of CO (Δm 28) or by further cleavage of the C–C bond next to N, giving an iminium ion. In 2-pyrrolidone and 2-piperidone, the signal at m/z 30 ($[CH_2=NH_2]^+$) is strong. The base peak of 2-pyridone is formed by CO elimination (Δm 28).

2-Pyrrolidone:

$C = X$

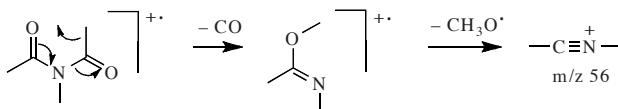

2-Piperidone:

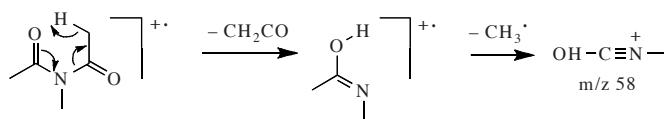

Molecular ion: Often observable; more abundant than for the corresponding lactones.

8.11.7 Imides

Saturated acyclic imides: Consecutive CO (Δm 28) and alkoxy elimination:

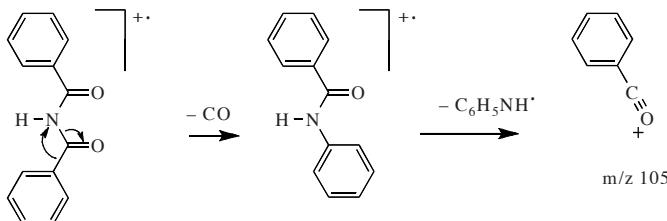

Ketene elimination:

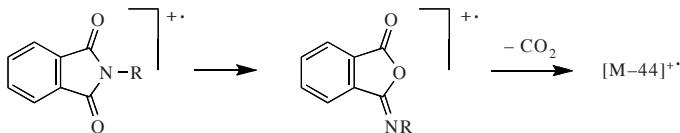

If the *N*-substituent chain is sufficiently long, cleavage of the C–C bonds next to N, with or without H rearrangement.

C=X

Dibenzoylamine: Loss of CO to *N*-phenylbenzamide:

Cyclic imides: The spectra of saturated cyclic imides are almost identical to those of the corresponding diketones. Loss of HNCO (Δm 43) from succinimide, followed by CO elimination (Δm 28). Aroyl migration and loss of CO_2 from aromatic cyclic imides.

C=X

8.12 Miscellaneous Compounds

8.12.1 Trialkylsilyl Ethers [1,2]

Fragmentation: Loss of alkyl attached to Si (preferential loss of larger groups). Cleavage of the C–C bond adjacent to O, followed by alkene elimination. Loss of alkoxy, followed by alkene eliminations. Elimination of trialkylsilanol. The $\text{R}_2\text{Si}-\text{OR}'$ cation has the tendency to attack, in an electrophilic manner and even over long distances, free electron pairs and π -electron centers, causing the expulsion of neutral fragments from the interior of the molecule via a rearrangement:

Ion series: $[\text{C}_n\text{H}_{2n+3}\text{OSi}]^+$ (m/z 75, 89, 103, 117, ...). $[\text{C}_n\text{H}_{2n+3}\text{Si}]^+$ (m/z 45, 59, 73, 87, ...). Occasionally, maxima at even mass due to elimination of trialkylsilanol.

Molecular ion: M^+ often of low abundance or absent, easily protonated to $[\text{M}+\text{H}]^+$. Typical isotope patterns owing to ^{28}Si , ^{29}Si , and ^{30}Si (see Chapter 2.5.5).

8.12.2 Phosphorus Compounds

Alkyl Phosphates [3]

Fragmentation: Maxima due to alkenyl loss from M^+ via double H rearrangement, followed by successive alkene eliminations down to protonated phosphoric acid (m/z 99).

Ion series: PO^+ (m/z 47), H_2PO_2^+ (m/z 65), H_2PO_3^+ (m/z 81), often as nonspecific P indicators.

Molecular ion: M^+ observable.

Aliphatic Phosphines

Ion series: Maxima of the ion series of $[\text{C}_n\text{H}_{2n+3}\text{P}]^+$ (m/z 48, 62, 76, 90, ...) due to alkene eliminations.

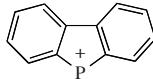

Molecular ion: M^+ observable.

P Si

Aromatic Phosphines and Phosphine Oxides

Fragmentation: Maxima due to loss of an aryl group, followed by H_2 elimination to yield the 9-phosphaphluorenyl ion (m/z 183).

Molecular ion: M^+ abundant, easily losing H^+ to give $[\text{M}-1]^+$.

m/z 183

8.13.2 Spectra of Common FAB MS Matrix and Calibration Compounds

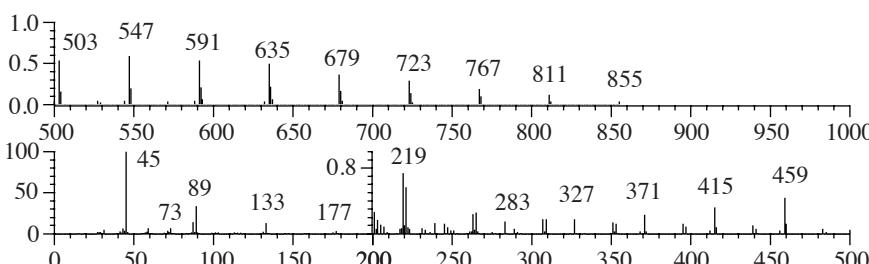

Fast atom bombardment (FAB) mass spectra (MS) usually exhibit signals for the protonated or deprotonated molecular ions, $[M \pm H]^\pm$, and protonated clusters, $[M_n + X_m \pm H]^\pm$ ($n, m = 0, 1, 2, \dots$), of the sample and matrix molecules, X. Even traces of metal salts in the sample give rise to clusters of the type $[M_n + X_m + \text{metal cation}]^\pm$. Na^+ (23 u) and K^+ (39 u) adducts are often found. The nature of the clusters is often revealed by the regular intervals at which their peaks occur in the spectra.

Calibration Compounds in Positive Ionization FAB Mass Spectra

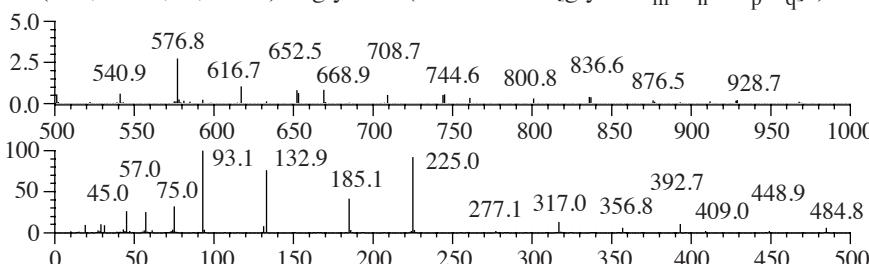

Ultramark 1621 (erroneously also referred to as perfluoroalkyl phosphazene)

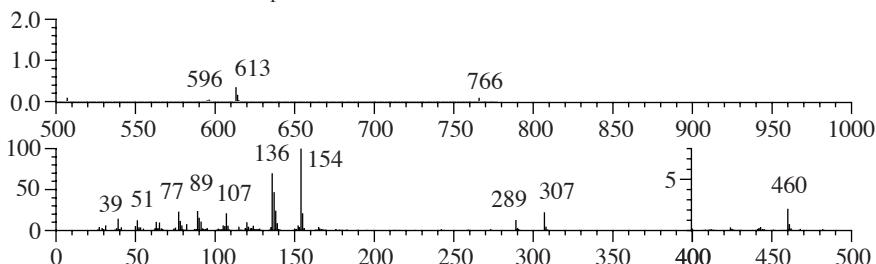

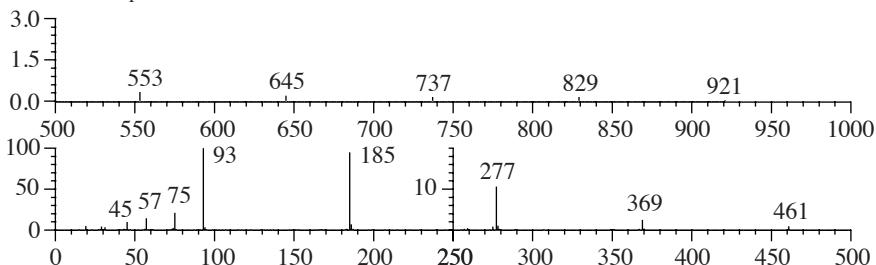

Polyethylene glycol 600 (often used as internal reference for high resolution m/z determinations)

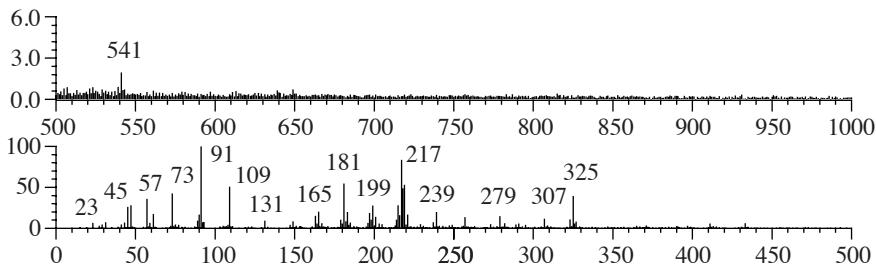

CsI (Cs^+ , 132.9; I^- , 126.9) in glycerol (formation of $[\text{glycerol}_m - \text{H}_n + \text{Cs}_p + \text{I}_q]^+$)

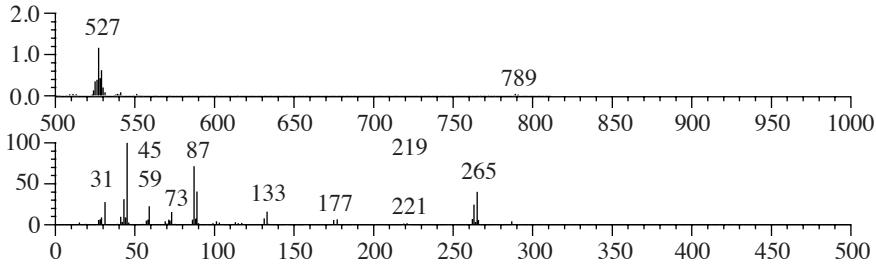

Solvents

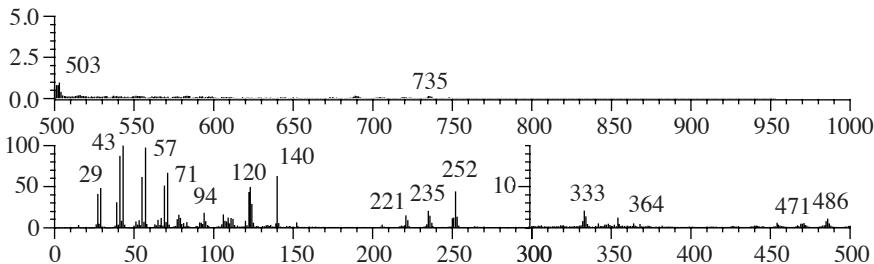

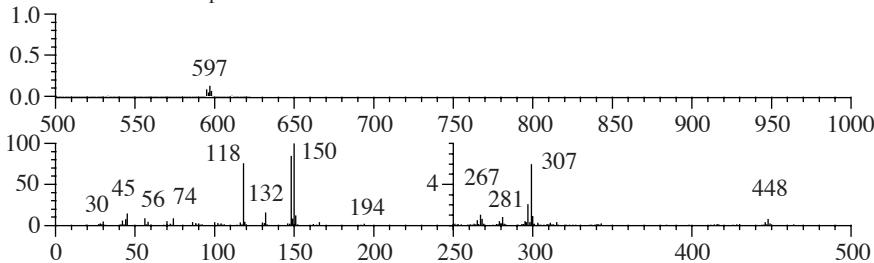

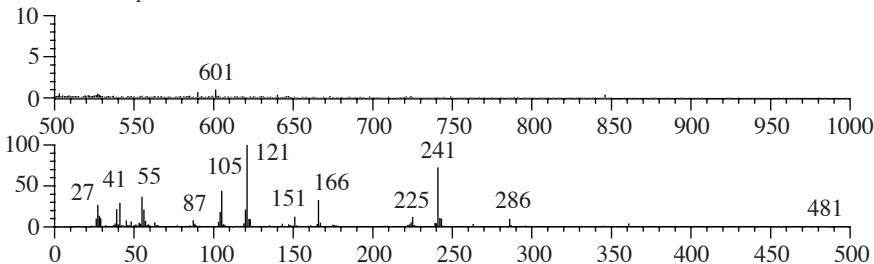

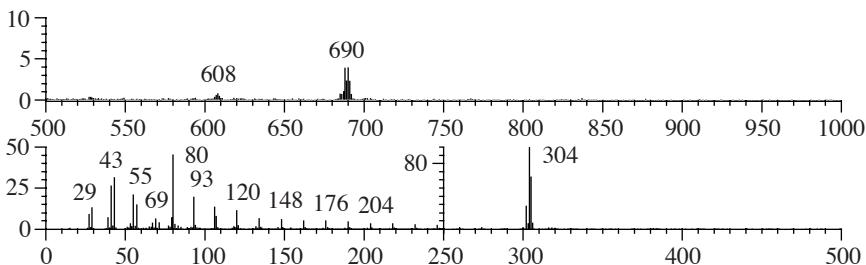

Matrix Compounds in Positive Ionization FAB Mass Spectra3-Nitrobenzyl alcohol (M_r 153.1)Glycerol (M_r 92.1)

1-Thioglycerol (M_r 108.2. Note m/z 23, Na^+ ; 131, $[\text{M}+\text{Na}]^+$; 239, $[\text{2M}+\text{Na}]^+$. Similarly, small K^+ impurities give signals at m/z 39, 147, 255)

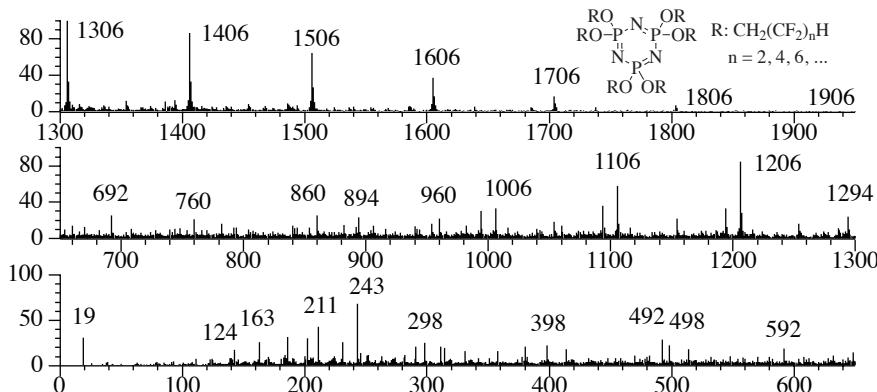

1,4,7,10,13,16-Hexaoxacyclooctadecane (18-crown-6, M_r 264.3. Also used as an additive; binds metal ions and reduces $[\text{M}+\text{metal ion}]^+$ in favor of $[\text{M}+\text{H}]^+$, which can be important for samples with exchangeable H^+ , such as for peptides [1])

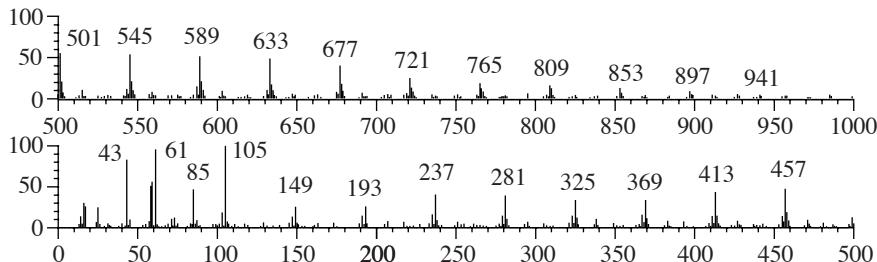

2-Nitrophenyl octyl ether (M_r 251.3)Triethanolamine (M_r 149.2)Sulfolane (M_r 120.2) [2]Hexadecylpyridinium bromide (M_r 384.4; for [hexadecylpyridinium]⁺ m/z 304.3) in 2-nitrobenzyl alcohol

Calibration Compounds in Negative Ionization FAB Mass Spectra

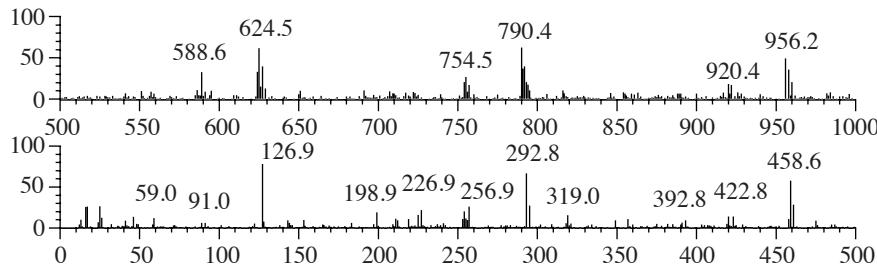

Ultramark 1621 (erroneously also referred to as perfluoroalkyl phosphazine)

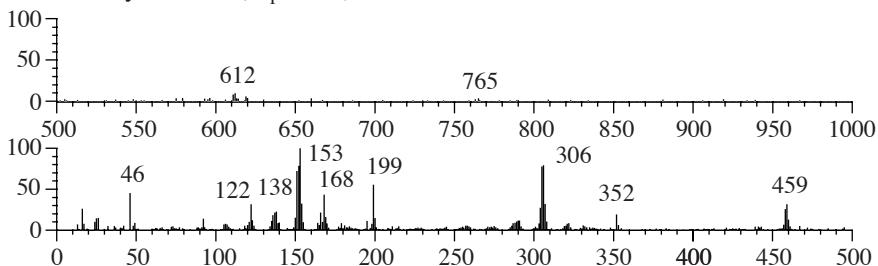

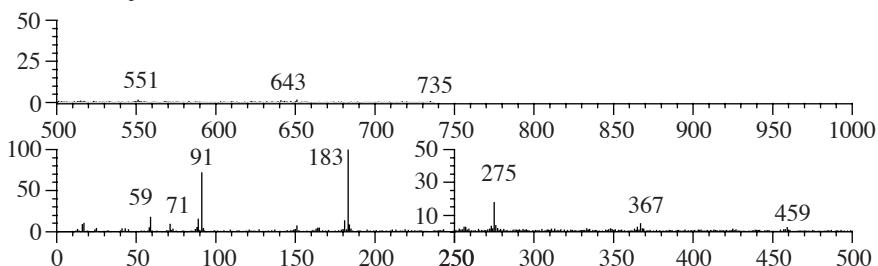

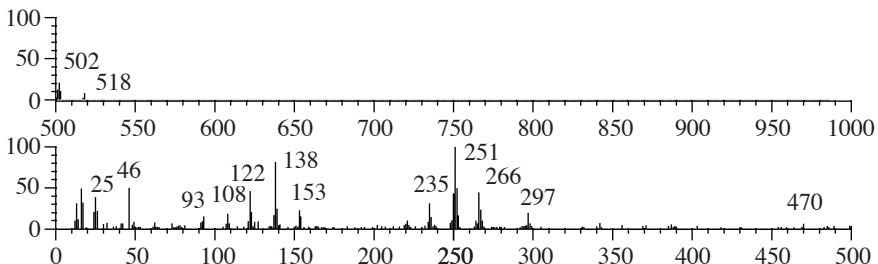

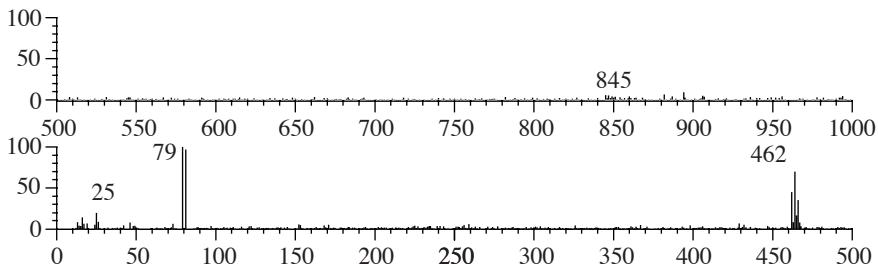

Polyethylene glycol 600 (often used as internal reference for high resolution m/z determinations)

KI ($\text{K}^+, 39.1$; $\text{I}^-, 126.9$) in glycerol (formation of $[\text{glycerol}_m\text{-H}_n\text{+K}_p\text{+I}_q]^-$)

Matrix Compounds in Negative Ionization FAB Mass Spectra3-Nitrobenzyl alcohol (M_r 153.1)Glycerol (M_r 92.1)2-Nitrophenyl octyl ether (M_r 251.3)2-Nitrobenzyl alcohol solution of hexadecylpyridinium bromide (M_r 384.4; enhances detectability and reduces metal ion adducts of sample [3])

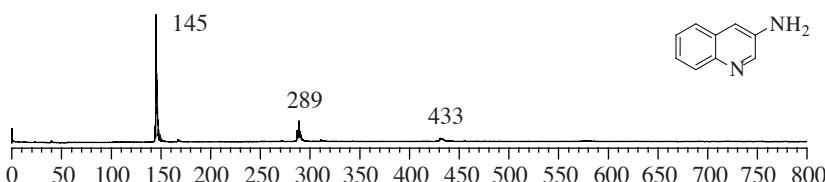

Solvents

8.13.3 Spectra of Common MALDI MS Matrix Compounds

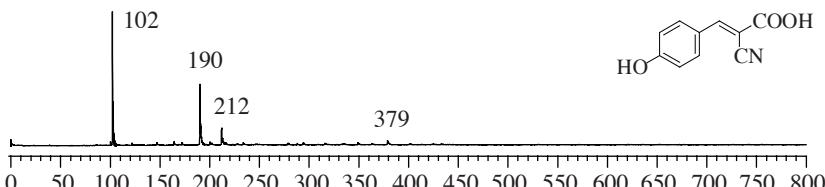

Matrix-assisted laser desorption ionization (MALDI) mass spectra (MS) usually show signals for protonated or deprotonated molecular ions, $[M \pm H]^\pm$, and protonated clusters, $[M_n + X_m \pm H]^\pm$ ($n, m = 0, 1, 2, \dots$), of the sample and matrix molecules, X. In positive ionization mass spectra, clusters of the type $[M_n + X_m + \text{metal cation}]^+$ occur even if there are only traces of metal salts in the sample. Sodium (23 u) and potassium (39 u) ion adducts are often encountered. The nature of the clusters is revealed by the regular intervals at which their signals occur in the spectra [4].

Matrix Compounds in Positive Ionization MALDI Mass Spectra

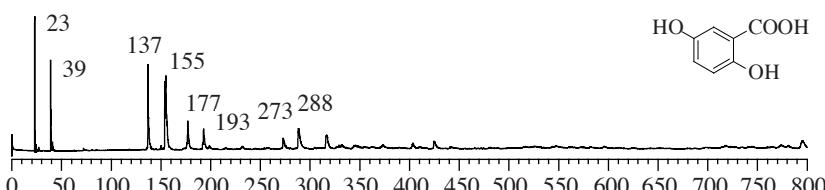

3-Aminoquinoline (M_r 144.2)

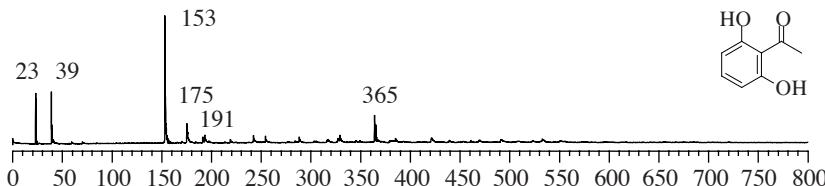

α -Cyano-4-hydroxycinnamic acid (M_r 189.2; m/z 212, $[M+Na]^+$)

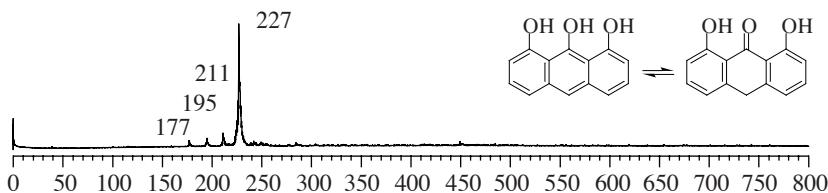

2,5-Dihydroxybenzoic acid (M_r 154.1; m/z 177, $[M+Na]^+$; m/z 193, $[M+K]^+$)

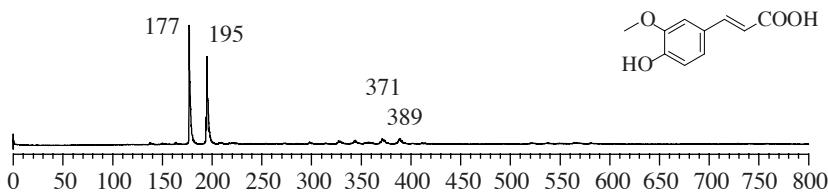

2,6-Dihydroxyacetophenone (M_r 152.1; m/z 175, $[M+Na]^+$; m/z 191, $[M+K]^+$; m/z 365, $[2M+Na+K-H]^+$?)

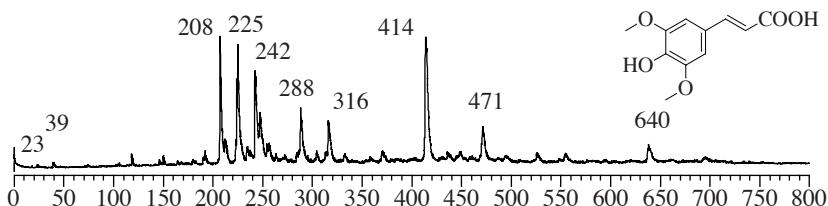

Dithranol (M_r 226.2)

Ferulic acid (4-hydroxy-4-methoxycinnamic acid; M_r 194.2)

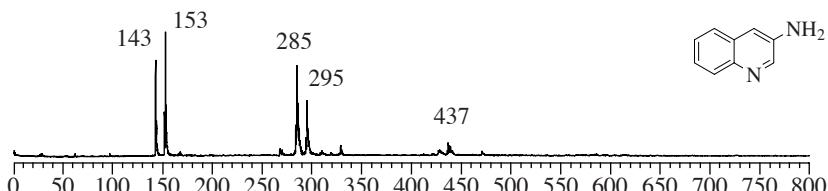

Sinapinic acid (3,5-dimethoxy-4-hydroxycinnamic acid; M_r 224.2; m/z 471, $[2M+Na]^{+}$)

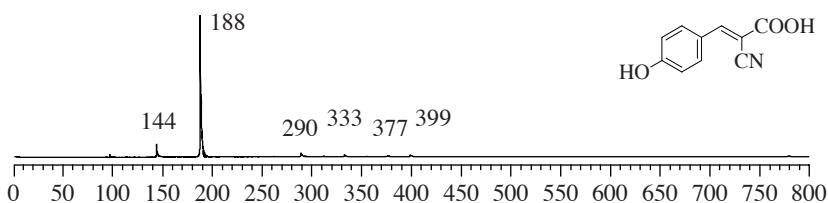

Matrix Compounds in Negative Ionization MALDI Mass Spectra

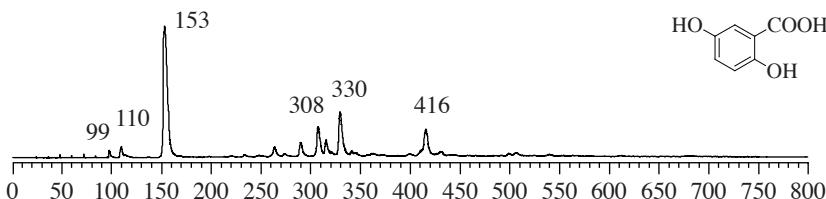

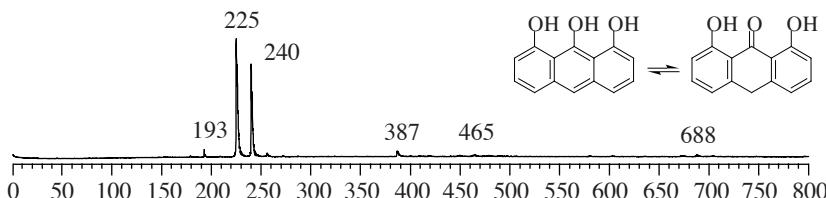

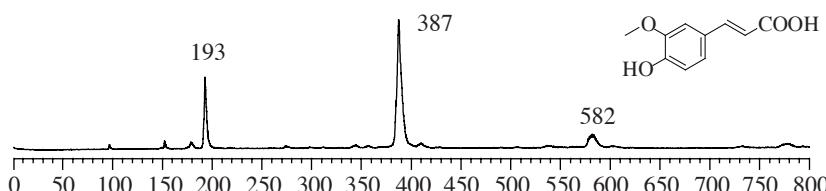

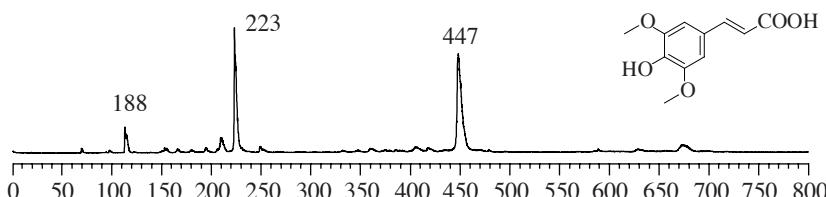

3-Aminoquinoline (M_r 144.2)

α -Cyano-4-hydroxycinnamic acid (M_r 189.2; m/z 399, $[2M+Na-2H]^{-}$)

Solvents

9.3 Conjugated Alkenes

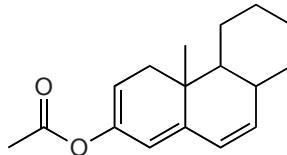

9.3.1 Dienes and Polyenes

The $\pi \rightarrow \pi^*$ transition of conjugated double bonds is above ≈ 200 nm with typical intensities of the order of $\log \epsilon \approx 4$. Its position can be estimated with the Woodward–Fieser rule. For cross-conjugated systems, the value for the chromophore absorbing at the longest wavelength has to be calculated.

Woodward–Fieser rule for estimating the position of the $\pi \rightarrow \pi^$ transition (λ_{\max} in nm)*

para-O-alkyl	25
estimated	274
experimental	276

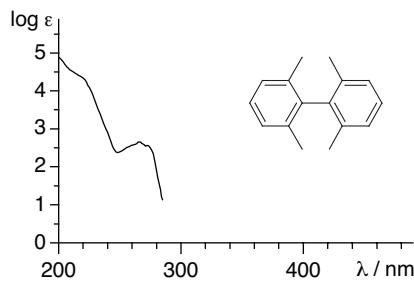

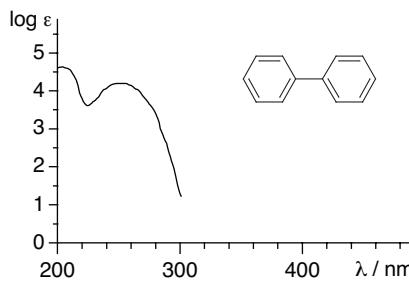

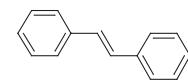

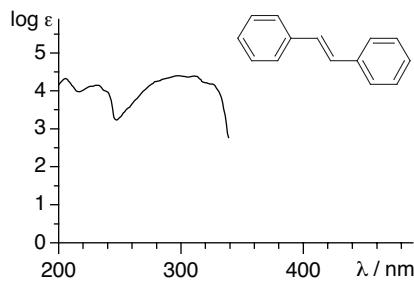

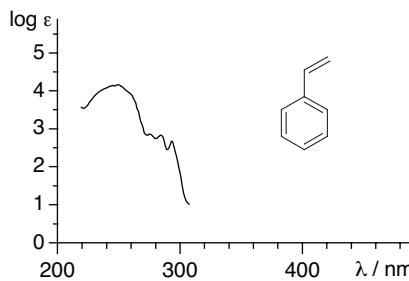

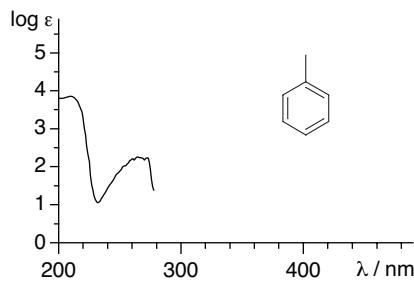

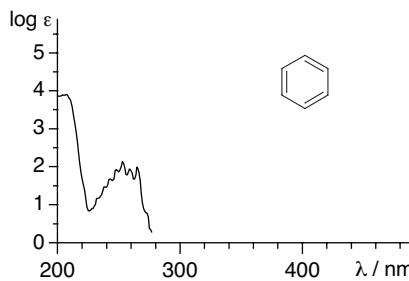

9.5 Reference Spectra

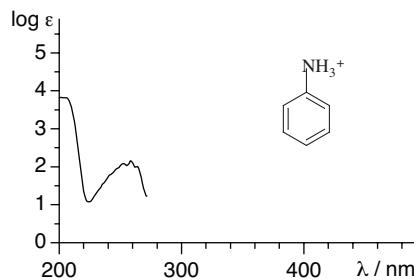

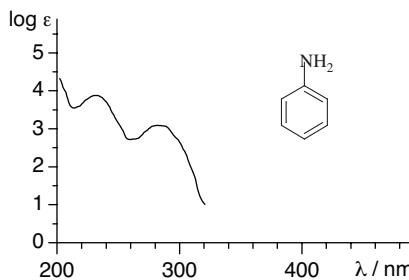

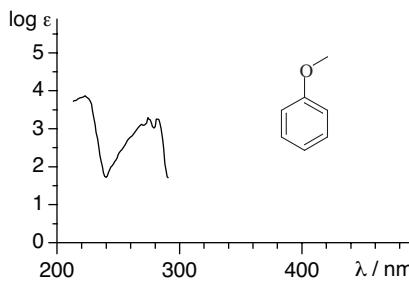

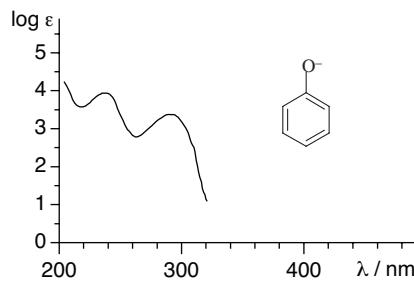

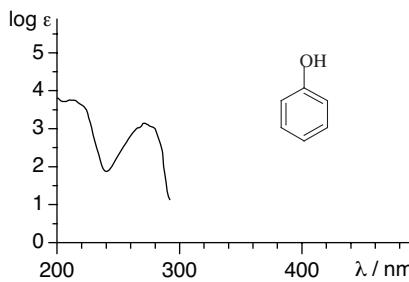

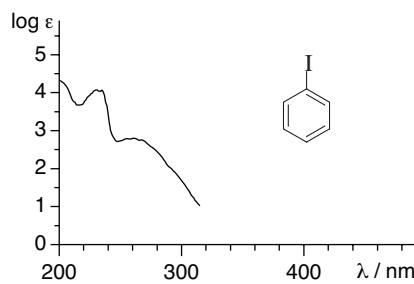

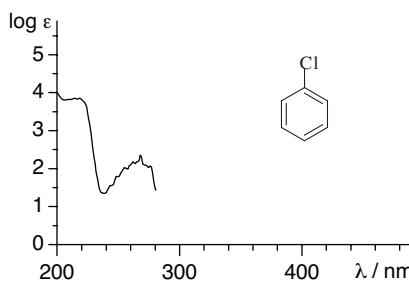

9.5.1 Alkenes and Alkynes

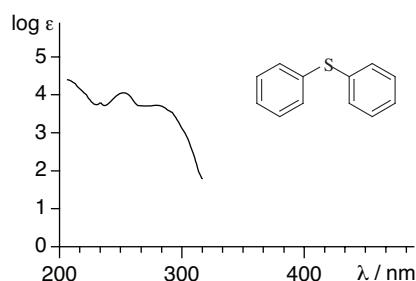

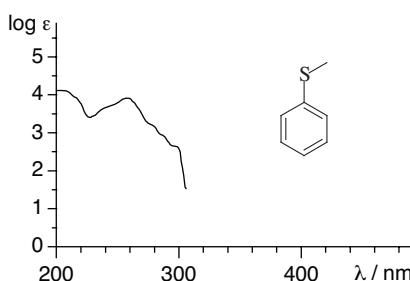

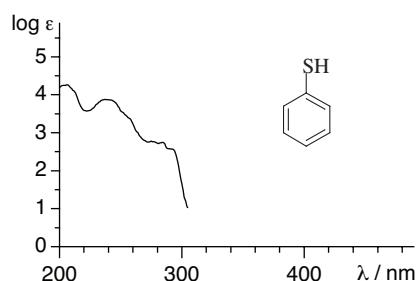

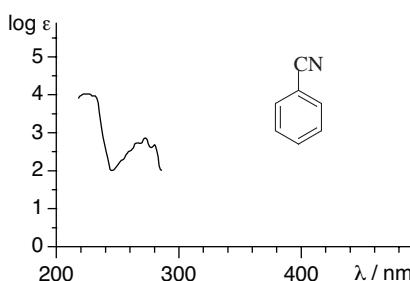

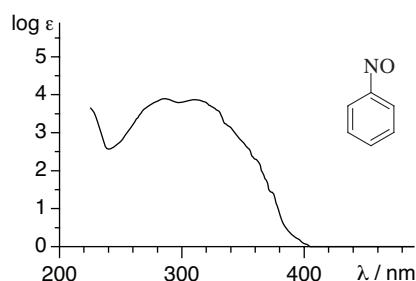

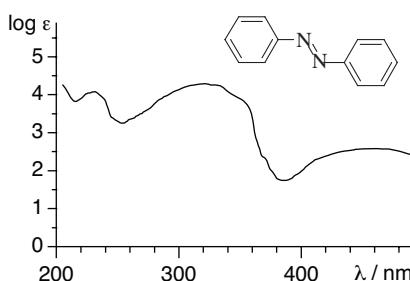

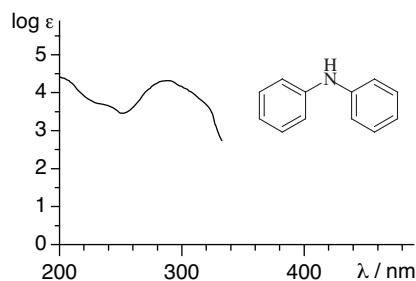

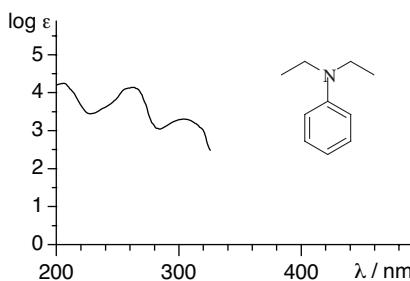

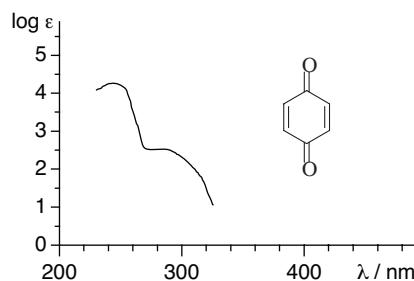

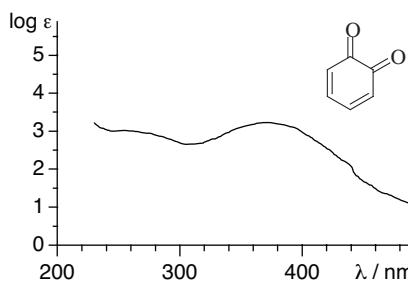

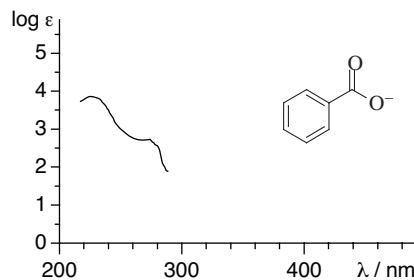

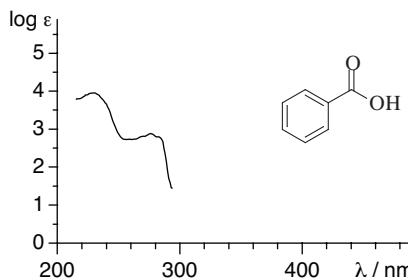

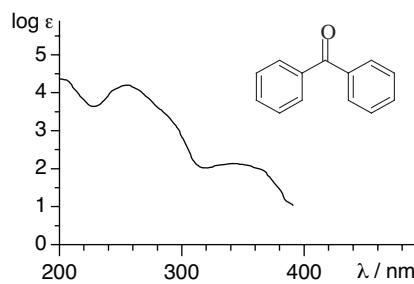

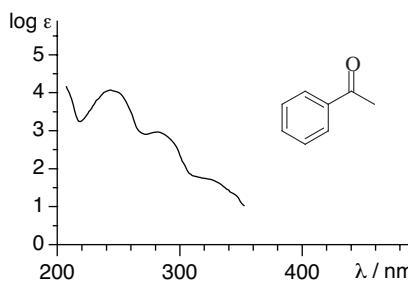

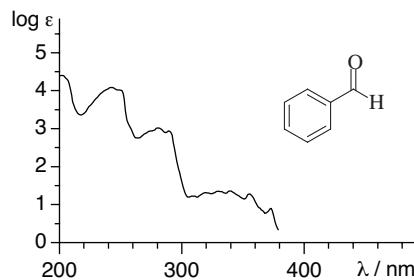

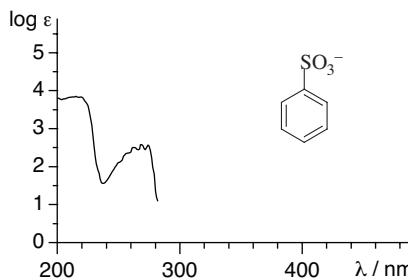

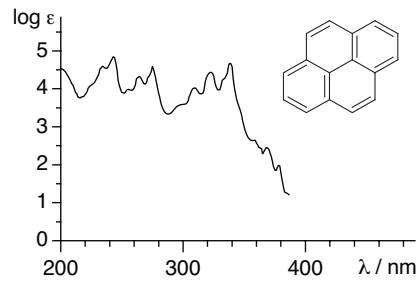

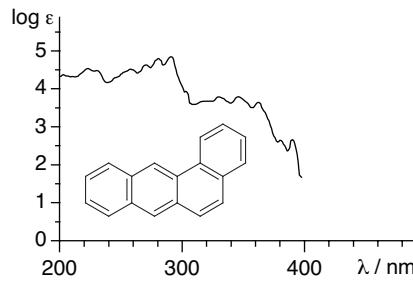

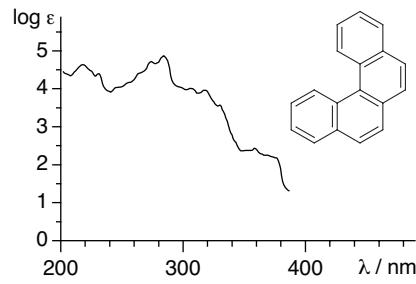

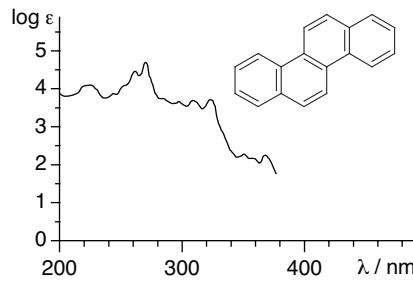

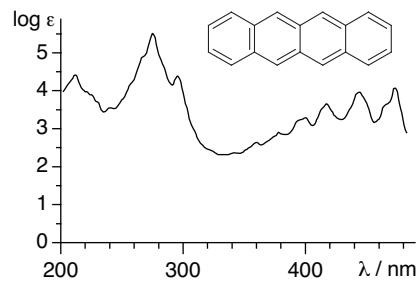

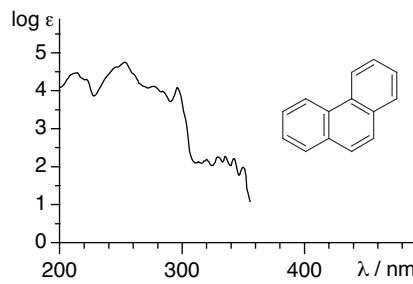

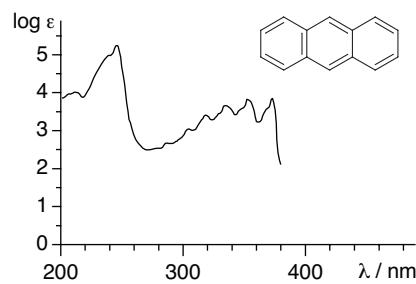

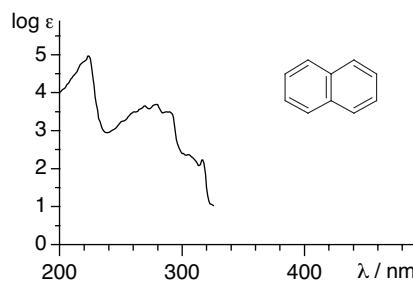

9.5.2 Aromatic Compounds

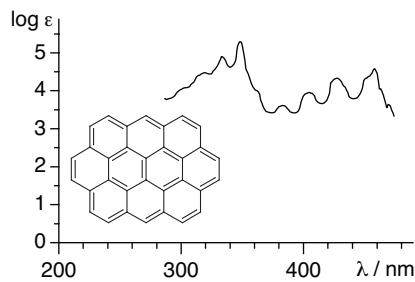

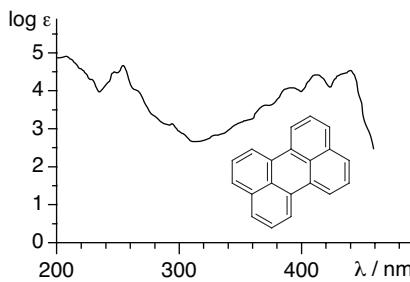

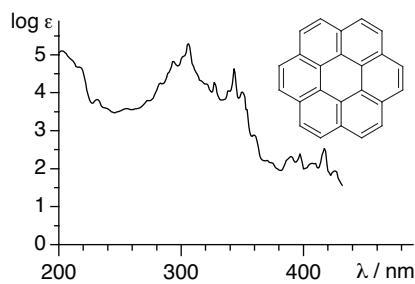

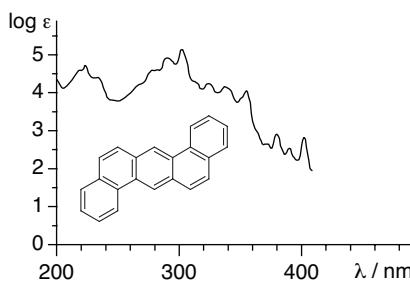

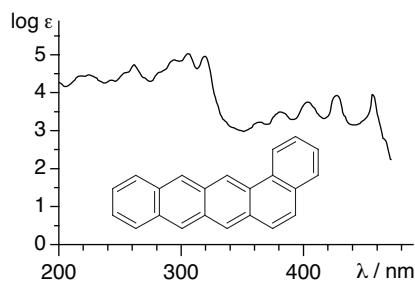

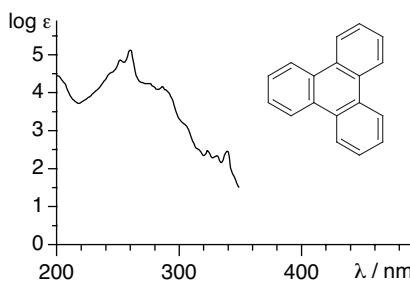

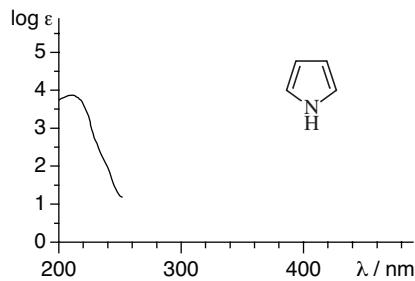

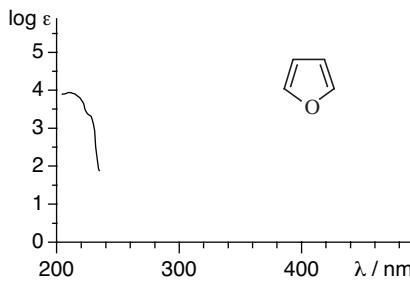

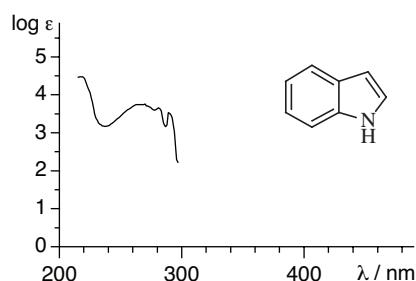

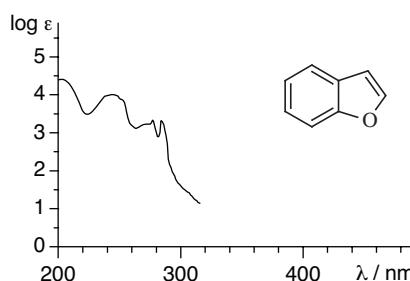

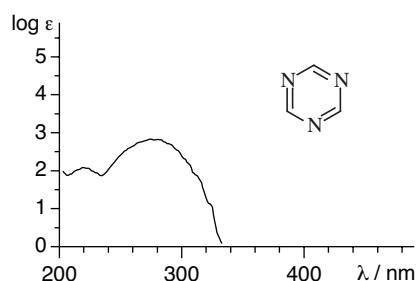

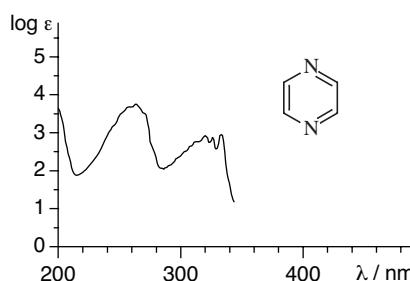

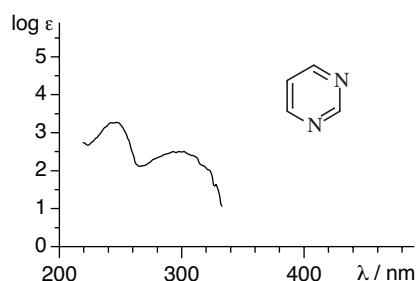

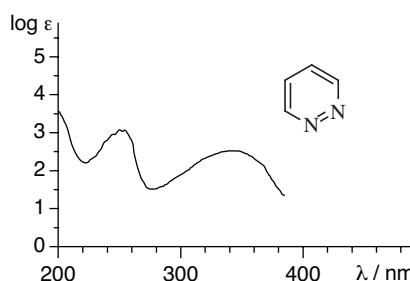

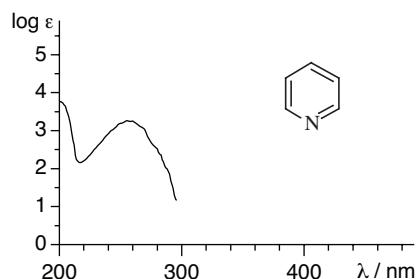

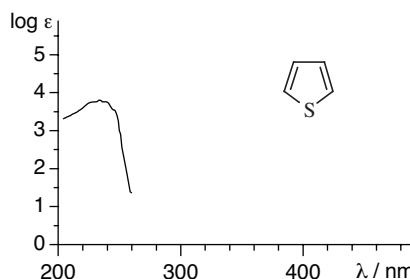

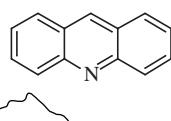

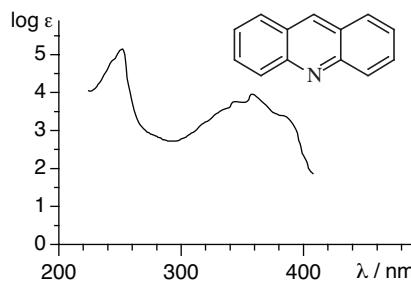

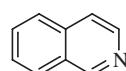

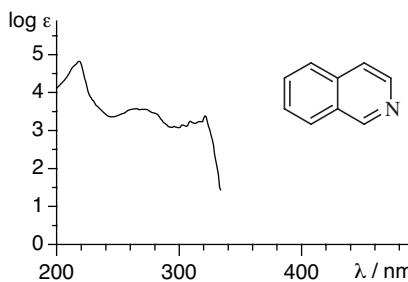

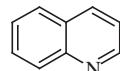

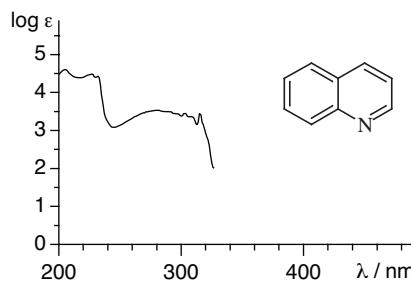

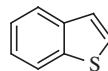

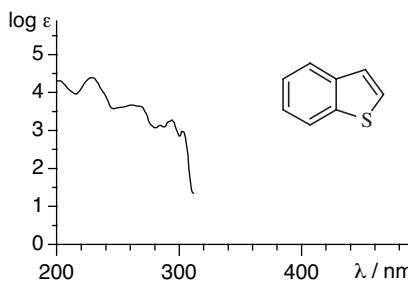

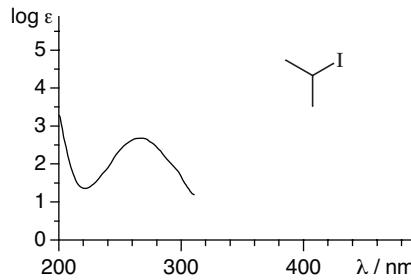

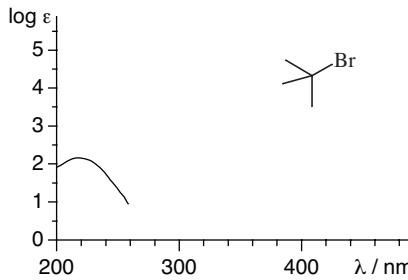

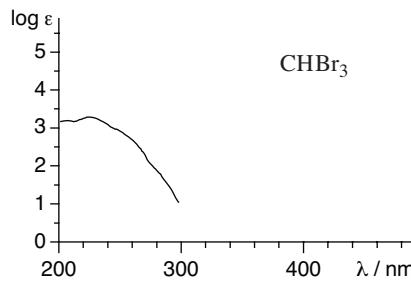

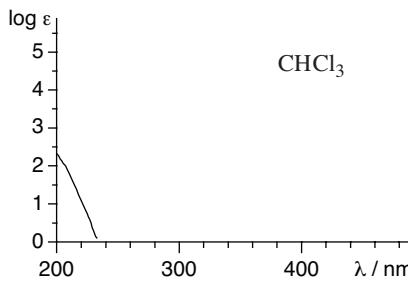

9.5.3 Heteroaromatic Compounds

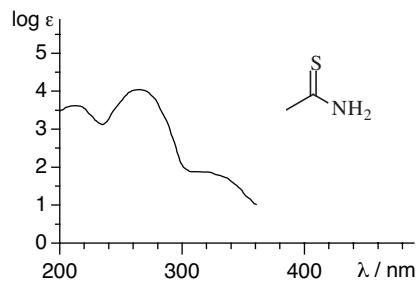

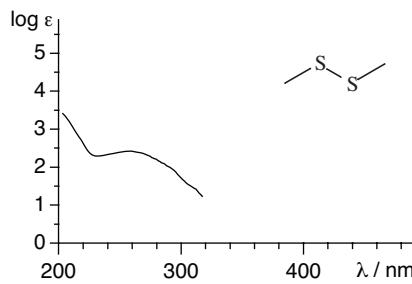

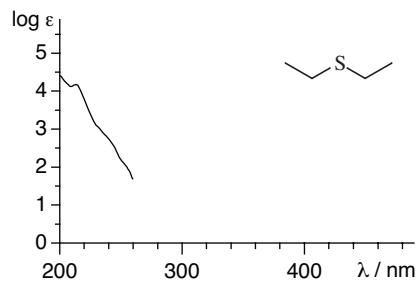

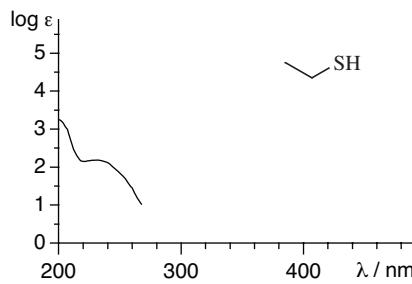

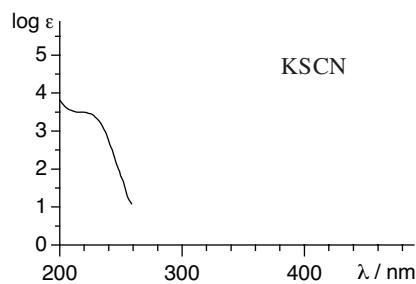

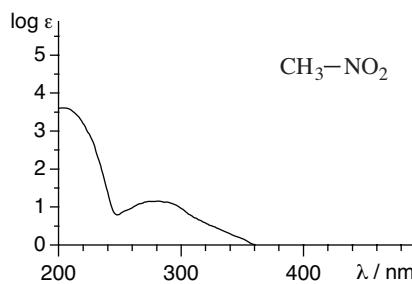

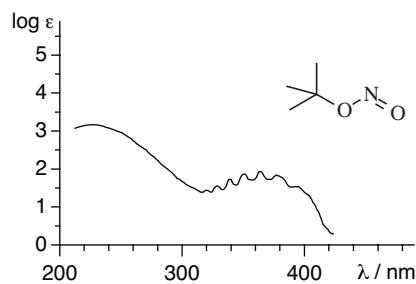

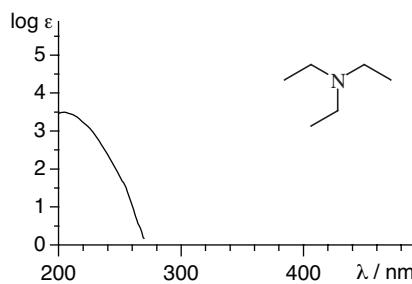

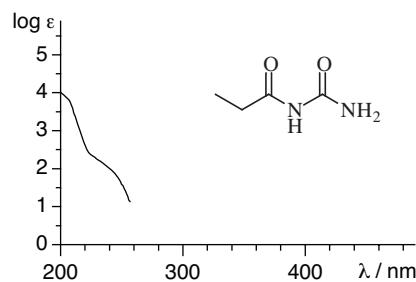

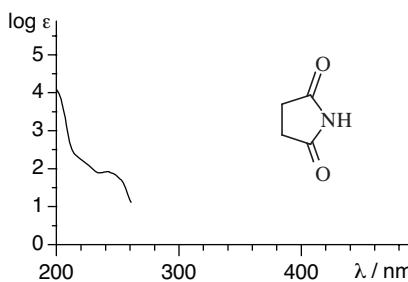

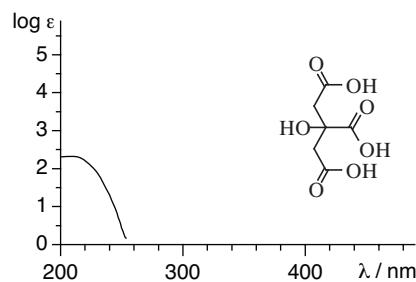

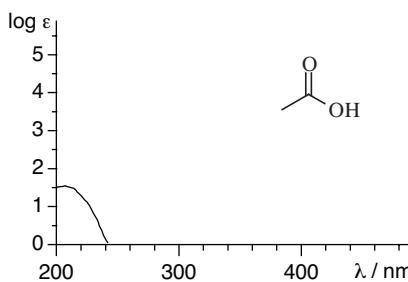

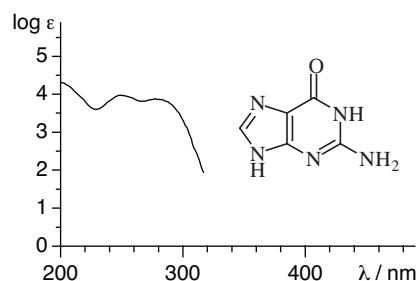

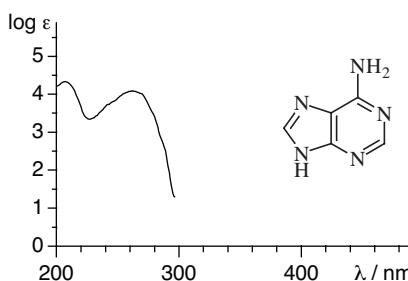

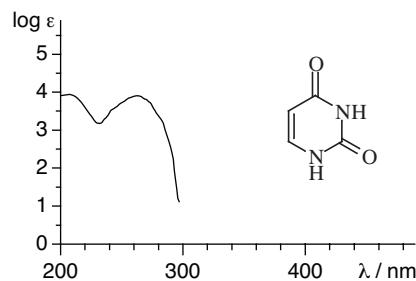

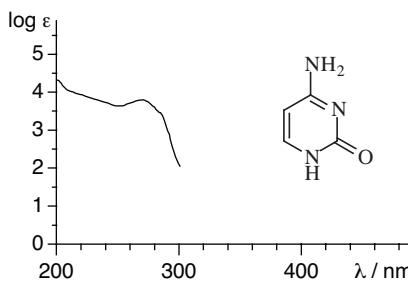

9.5.4 Miscellaneous Compounds

9.5.5 Nucleotides

9.6 Common Solvents

The end absorption, λ_{end} , of several common solvents is given here as the wavelength at which the solvents absorb 80% of the irradiated light (λ_{end} in nm; cell length, 1 cm; reference, water).

Solvent	λ_{end}	Solvent	λ_{end}
acetone	335	ethyl acetate	205
acetonitrile	190	heptane	195
benzene	285	hexane	195
carbon disulfide	380	methanol	205
carbon tetrachloride	265	pentane	200
chloroform	245	2-propanol	205
cyclohexane	210	pyridine	305
dichloromethane	230	tetrahydrofuran	230
diethyl ether	210	toluene	285
1,4-dioxane	215	2,2,4-trimethylpentane	210
ethanol	205	xylene	290

Subject Index

- Absorbed radiation and observed color
U401
- Acenaphthene C93, H181
- Acenaphthylene C93, H181
- Acetaldehyde C128, H216, I311
- Acetaldoxime H209, I298
- Acetals C116, H204, I269, I288–I289
- Acetamides C135, H222, I321
- Acetanilide C136, H223, I321, M385
- Acetate ion C132, I315
- Acetic acid C131, H218, I315, M390, U419
- esters C133, H219, I318
- Acetic anhydride C137, H224, I322
- Acetoisonitrile C122, H211
- Acetone C79, C129, C156, H217, H242, M390, U420
- Acetone-*d*₆ C153, H239
- Acetonitrile C122, C156, H210, H242, M390, U420
- Acetonitrile-*d*₃ C153, H239
- Acetophenone C129, H209, I313, M381, U406, U408, U413
- Acetyl
- bromide C137, H224
- chloride C137, H224
- fluoride C137
- iodide C137, H224
- Acetylacetone C83, C115, C131, H202, H218, I313
- Acetylenes C85, C86, H172, I270, I276, M341, U401
- Acetylenic ethers C85, H172, M357
- Acid halides C137, H224, I323
- Acids 64, C131–C132, H218, I314, M381–M384, U402
- Acridine C107, H195, U417
- Acrylaldehyde C128, H216, H218, I275, U404
- Acrylate ion C132
- Acrylic acid C131, H218, I275, U404
- Acryloisonitrile C122, H211
- Acrylonitrile C122, H210, I275, I299
- Acryloyl chloride C137, H224
- Adamantane C91, H174
- Adenine C150, H237, U419
- Adenosine C151, H238
- Alanine C144, H232, I316
- β-Alanine C144
- Alcohols 56, C114, H200, X254, I287, M354–M356, U402
- Aldehydes 62, C128, H216, I269, I310, M379
- α,β-unsaturated I275, I311, U404
- Aldimines C120, H209, I297
- Aldoximes C121, H209, I298
- Alicyclic ketones C130, H217, I312–I313, M380
- Alicyclics C87, C90, H173, X250, I271, I277, M342, M343
- condensed C91
- polycyclic C91, M343
- saturated monocyclic I278, M342
- unsaturated C90, I278
- Aliphatic amides H222, I321
- Aliphatic esters I317
- Alkanes 49, C69, C72, C73, H157–H161, X248, I269, M337
- aromatically substituted H161
- branched I270, M337
- cyclic 49, C87, H157–H161, X248, I269, I271, I277, M337
- monosubstituted C72–C73, H158–H159
- polycyclic M343
- unbranched M337
- Alkenes 50, C80, H164, I270, I272, M339, U401, U409

- branched M339
- conjugated U403
- cyclic I277–I278
- unbranched M339
- Alkynes 51, C85, H172, X249, I270, I275, I276, I313, M341, U401, U409
- Allenes C83, H171, X249, I275, U401
- Allyl alcohol C114
- Allylamine C118
- Amide I and II bands I320
- Amide protons H220
- Amides 67, C135, H220, I319, M384, U402
- Amines 59, C117, H205, I269, I292, M362
 - alkenyl-substituted I275
- Amino acids C144, H232, I332
- 3-Aminoquinoline M398, M399
- Ammonium protons H205
- Ammonium salts C117, H205, I292
- Androstane C152
- Anhydrides C137, H224, I322, M382
- Anilides M385
- Aniline C118, H207, I294, U411
- Anilinium ion U411
- Anisole C115, H177, H204, I290, U411
- Anthracene C93, H177, U414
- Anthraquinone I314
- Antimony compounds C143
- Arenes C93, H177, I279, M345
- Arginine C147, H234
- Aromatic
 - amines C118, H205, H207, M364, U407
 - carbonyl compounds U408
 - compounds U410
 - esters C133–C134, I317

- Azobenzenes C120, H209, M365, U412
- Azo compounds C120, H208, I298, U402
- Azomethane H209
- Azothio compounds I298
- Azoxy compounds C120, H208, I298
- Azulene C93, H174
- Benzaldehydes C128, H216, I311, U413
- Benzene C93–C94, C100, C115, H177, H180, I280–I281, M391, U406–U407, U410, U420
 - monosubstituted C94, H178, I280–I281
 - coupling constants H180
 - Benzene-*d*₆ C153, H239, M391
- Benzenesulfonamide C126, H215, M377
- Benzenesulfonic acid C126, H215, M376
- Benzenesulfonyl chloride C126, H215
- Benzenthiol C123, H212, M371
- Benzimidazole C106, H191
- Benzoate ion C132, U413
- Benzo[b]furan C106, H191
- Benzo[b]thiophene C106, H191
- Benzodioxine H193
- Benzodithiine H193
- Benzoic acid C131, H218, I316, U406, U413
- Benzoic anhydride C137, H224, I322
- Benzonitrile C122, H210, I299, U406, U412
- Benzophenone C129, H217, I313, U413
- Benzoquinones C130, I314, U413
- Benzothiadiazole C106, H192
- Benzothiazole C106, H191
- Benzotriazole H192
- Benzoxadiazole C106, H192
- Benzoxazole C106, H191
- Benzoyl chloride C137, H224
- Benzyl alcohols C115, H201, I288, M356
- Benzylamine C118, M364
- Benzyl mercaptan C123, I304

- Bicyclo[2,2,1]heptane H174
 Bicyclo[2,2,2]octane C91
 Biphenyl M345, U410
 Bismuth compounds C143
 Boron compounds C143, H231, I331
 Bromoacetylene H198
 Bromobenzenes C112, H198, I285
 Bromo compounds C112, H198, I286, I323, M352, U401
 Bromocyclohexane C112, H198
 Bromocyclopropane H198
 Bromoethane C112, H198
 Bromoethylene C112, H198
 Bromoform C112, H198, U417
 Bromoform-d C153, H239
 Bromomethane C112, H198
 Bromopyridines C112
N-Bromosuccinimide H225, I321
 Butadiene C84, H170
 Butane C69, H157
 Butanedione C131, H218
 Butanethiol H212, I304
 Butanol I288
 Butanone C129, H217
 Di-*tert*-butyl
 – disulfide H214, I304
 – ketone C129, I311
 – sulfide H213
 – sulfone H214
 – thionketone C127
 Butyl
 – acetate H219, M391
 – isocyanate C122, H211
N-*tert*-Butyl
 – acetamide C136, H222
tert-Butyl
 – acetate C133, H219
 – alcohol C114, H201
 – aldehyde C128, H216
 – amine C117
 – bromide C112, H198, U417
 – chloride C111, H197
 – fluoride C109, H196
 – iodide C113, H199
 – methyl ether C115, H202
 – methyl ketone C129, H217
 – thiol C123, H212
 Butyraldehyde C128, H216
 Butyric acid C131, H218
 Butyric anhydride C137, H224, I322
 γ -Butyrolactam C136, H223
 γ -Butyrolactone C134, H220, I317
 Butyronitrile C122, H210
 Calibration compounds M393
 ϵ -Caprolactam C136, H223
 ϵ -Caprolactone C134
 Carbamates C138, H225, I324–I325
 Carbazole C107, H195
 Carbodiimides C121, U402
 Carbohydrates C148, H235
 Carbon
 – dioxide C138, I335
 – disulfide C138, I334, M391, U420
 – monoxide C138
 – tetrabromide C112
 – tetrachloride C111, I333, M392, U420
 – tetrafluoride C109
 – tetraiodide C113
 Carbonate ion C138
 Carbonic acid
 – derivatives C138, H225, I324
 – esters C138, H225, I324
 Carbonyl compounds 62, C128, H216, I310, M379
 – α,β -unsaturated I312–I314, U404
 Carboxylate anions C132, H218, I314
 Carboxylic acids 64, C131, H218, I275, I314, M381, U402
 – amides I319
 – anhydrides C137, I321, M382
 – esters 65, I316
 – halides C137, I323

Cholesterol C152
Chromone H193
Chromophores U401
Cinnoline C107, H194, M350
Citric acid U419
¹³C NMR spectroscopy C69
Condensed heteroaromatics C106, H191–H195
Conjugated dienes H170, I275, U403
Coronene H177, U415
Coumarin H193
Coupling
– with ¹⁴N C122, H205
– with ²⁹Si H226
– with hydroxy protons H200
– with NH protons H221
– with SH protons H212
Crotonic acid I316
– esters I318
18-Crown-6 M394
CsI in glycerol M393
Cubane C91
Cyanates H211, I301, M367
Cyanides C122, H210, I270, I299–I300, M366, U402
α-Cyano-4-hydroxycinnamic acid M398, M399
Cyclic
– alkanes C87, H173, I269, I271, M342
– alkenes C90, H173–H174, I272, I277, M343
– amines C119, H207, M363
– anhydrides C137, H224, I322
– ethers C116, H203, I289, M358
– imides C138, H224, I321, M387
– ketones C130, H217, I312, M380
– sulfides C124, H213, M372
– sulfones C125, H214, M375
Cycloalkanes C87, H173, I269, I271, I277, M342
Cycloalkenes 50, C90, H173, I272, I277, M343
Cycloalkylamines M362
Cyclobutane C87, C92, H173, I278
Cyclobutanone C130, H217, I312
Cyclobutene C90, H173
Cyclobutenes I272, I278
Cycloheptadiene C90
Cycloheptane C87, I278
Cycloheptanone C130, I312
Cycloheptatriene C90, H174
Cycloheptene C90, H173
Cyclohexadiene C90, H173, M343
Cyclohexanecarbonitrile C122, H210
Cyclohexanecarbonyl chloride C137
Cyclohexanecarboxaldehyde C128
Cyclohexanecarboxylate ion C132
Cyclohexanecarboxylic acid C131
Cyclohexane-*d*₁₂ C154, H240
Cyclohexanes C87, C92, H173, I278, M391, U420
– monosubstituted C89, H176
Cyclohexanethiol C123, H212
Cyclohexanol C115, H201, I288
Cyclohexanone C130, H217, I312, M380
Cyclohexanone oxime C121, H209
Cyclohexene C90, H173
Cyclohexenes I272, I278, M343
Cyclohexyl
– acetate C133
– methyl ether C115
– methyl ketone C129
Cyclohexylamine C118, I294
– 4-*tert*-butyl H206
Cyclooctadiene C90, H174
Cyclooctane C87, I278
Cyclooctatetraene C90
Cyclooctene C90, H174
Cyclopentadiene C90, H173
Cyclopentane C87, C92, H173, I278
– monosubstituted C88
Cyclopentanone C130, H217, I312

- Cyclopentanone oxime H209
 Cyclopentenes C90, H173, I272, I278
 Cyclopropanecarbonitrile H210
 Cyclopropanes C87, C92, H173, I269,
 I272, I274, I275, I278, I312, M342
 – monosubstituted C87, H175
 Cyclopropanol C87, H201
 Cyclopropanone H217
 Cyclopropenes C90, H173, I272, I278
 Cyclopropenone C130
 Cyclopropylamine C87, H206
 Cysteine C145, H233
 Cystine C145
 Cytidine C150, H237
 Cytosine C150, H237, U419
- Decalins C91
 Deoxyadenosine C151, H238
 Deoxyguanosine C151, H238
 Deuterated solvents C153, H239
 DFTMP 3, H226, H231
 Diacetamide C138
 Diacetyl C131, H218
 Diacylperoxides I291

Fluoroacetylene H196, X249
Fluorobenzenes C110, H196, X251
Fluoro compounds C109, H196, X243, I284, I323, M352
Fluorocyclohexane C110, H196, X250
Fluorocyclopropane H196, X250
Fluoroethane C109, H196, X245
Fluoroethylenes C109, H196, X247
Fluoromethane C109, H196, X245
Fluoronaphthalene H197
Fluorooctane C109
Fluoropropane C109, H196, X245
Fluoropyridine C110, X252
 ^{19}F NMR spectroscopy X243
Formaldehyde C128, H216
Formamides C135, H221, I321
Formanilide H222, M385
Formate ion C132
Formic acid C131, H218, I315
Formic anhydride C137
Fructose C149, H236
Fullerene C93
Fulvene C90, H173, I278
Fumaric acid C132
Furans C101, C108, H184, I282–I283, M347, M390, U415
– monosubstituted H186

Geminal coupling constants H162, H164
Geminal methyl groups I270
Germanium compounds C139, H227
Glucose C148, H236
Glutamic acid C146, H233
Glycerol C114, M394, M397
Glycine C144, H232
Glycols C114, M355
Guanine C150, H237, U419
Guanosine C151, H238

Halobenzenes I285
Halogenated ketones C130, I312
Halogen bonding X246
Halogen compounds 54, C109, H196, I284, I323, M352, U401
Heptane C69, U420

Heteroaromatics 53, C101, H184, I282, M347, U415
– condensed C106, H191–H195
Heteroatom indicators 32
Hexachloroethane C111
Hexadecylpyridinium bromide M395, M397
Hexane C69, M391, U420
1-Hexene M391
Histidine C147, H235
 ^1H NMR spectroscopy H157
Homoallylic coupling H165
Homologous mass series 35
Hydrazides I320
Hydrazones C121
Hydroperoxides I291, M356
Hydroxyl protons
– coupling H200
– exchange H200
4-Hydroxyproline C147, H234

Imidazole C101, C108, H184
Imidazole anion C101
Imidazolium cation C101, H184
Imides C138, H224, I320, M386
Imines C120, H209, I296
Indane C92–C93, H181
Indazole C106, H192
Indazoline C106
Indene C92, C93, H181
Indole C106, H191, U416
Indoles M349
myo-Inositol H235
Interferences in IR spectra I335
Iodides C113, H199, I286, I323, M352, U402
Iodobenzenes C113, H199, I285, U411
Iodo compounds C113, H199, I286, I323, M352, U402
Iodocyclohexane C113, H199
Iodocyclopropane C87, H199
Iodoethane C113, H199
Iodoethylene C113, H199
Iodoform C113, H199
Iodomethane C113, H199
Iodonaphthalene H199
Iodopyridine C113
IR spectroscopy I269

- Isocyanates C122, H211, I301, M367
Isocyanides C122, H211, I299, M366
Isocyanurates I320
Isoleucine C144, H232
Isonitriles C122, H211, I299, M366
Isopropanol C114, H201, U420
Isopropyl acetate C133, H219
Isoquinoline C107, H193, U417
Isoquinoline-*N*-oxide H194
Isoquinolines M350
Isothiazole C101, H184
Isothiocyanates C122, H211, I302, M369, U402
Isotope patterns
– calculation of 27
– for combinations of Cl, Br, S, and Si 29–30
– for elements 26
Isotopes
– abundance of 18–19
Isotope substitution I271
Isoxazole C101, H184
- Karplus equation H163
Ketals C116, H204, I288–I290

 Tripropyl borate H231
 Trithiane C124, H213
 Trithiocarbonates C127, H225, I307, I309, I325–I326
 Trivinylphosphine H228
 Tropylium ion M345, M356
 Tryptophan C147, H235
 Twistane C91
 Tyrosine C146, H233
 Ultramark M393, M396
 Unsaturated alcohols M355
 α,β -Unsaturated carbonyl compounds I275, I311, I313–I314, I321–I323, U404, U409
 α,β -Unsaturated esters I317
 Unsaturated ethers I274, I290, M357
 Uracil C150, H237, U419
 Ureas C138, H225, I325, U402
 Urethanes C138, H225, I324–I325
 Uridine C150
 UV/Vis Spectroscopy U401
 δ -Valerolactam C136, H223
 δ -Valerolactone C134, H220, I317
 Valine C144, H232
 Vicinal coupling constants H162, H164
 Vinyl
 – acetate C133, H219
 – alcohol C115
 – compounds C81
 – esters I317
 – ethers I273, M357
 – isocyanate C122, H211, I302
 – isocyanide C122, H211
 – lithium C142, H230
 – magnesium iodide H231
 – mercury bromide H231
 – N-Vinyl
 – acetamide C136
 Volume susceptibilities C155
 Water- d_2 H241
 Water in chloroform I335
 Water vapor I335
 W-coupling H174
 Woodward–Fieser rule U403
 Xanthates I308, I309
 Xanthone H195
 Xylene U420
 Xylose H235
 Zwitterions I332
